We print this list with the realization that it may be outdated as soon as published, but once compiled it should be easier to keep up to date than if it remained an item in our files. We believe that members and others in the profession will find it useful and will help us improve it.

NOTE: AACSB and date after certain schools of business represent when they became members of the American Association of Collegiate Schools of Business. Dates of founding are indicated for university research divisions specializing in industrial relations.

Univ. of California:

Chmn.—Malcolm M. Davison
Dean—Ewald T. Grether, School of Bus. Admin. (AACSB, 1916)

Dir.—Clark Kerr, Inst. of Ind. Rela. (1945)

Univ. of California at Los Angeles:

Dean—Neil H. Jacoby, Col. of Bus. Admin. (AACSB, 1939)

Dir.—Edgar L. Warren, Inst. of Ind. Rela. (1945)

California Inst. of Tech.: Dir.—Robert D. Gray, Ind. Rela. Sec. (1939)

Carnegie Inst. of Tech.: Chmn.—George L. Bach
Catholic Univ. of America: Chmn.—Paul J. Fitzpatrick

Univ. of Chattanooga: Chmn.—William H. Weston, Jr.

Univ. of Chicago:

Chmn.—Theodore W. Schultz
Dean—Garfield V. Cox, School of Bus. (AACSB, 1916)

Dir.—Robert K. Burns and F. H. Harbison, Ind. Rela. Center (1945)

Univ. of Cincinnati:

Chmn.—William W. Hewett
Dean—Francis H. Bird, Col. of Bus. Admin. (AACSB, 1919)

City Col. of New York: Dean—Thomas L. Norton, School of Bus. and Civic Admin.

Claremont Colleges: Pres.—George C. S. Benson, Claremont Men's College

Clark Univ.: Chmn.—James A. Maxwell
Clemson Col. and South Carolina Agric. Exp. Sta.:

Chmn.—George H. Aull

Coe Col.: Chmn.—C. Ward Macy

Colby Col.:

Chmn.—Walter N. Breckenridge
Curtis H. Morrow

Colgate Univ.: Chmn.—Wilfred H. Crook

College of the Pacific: Chmn.—Charles B. Norman
Univ. of Colorado:

Chmn.—Earl C. Crockett
Dean—Elmore Peterson, School of Bus. (AACSB, 1938)

Colorado A & M Col.: Chmn.—Raymond T. Burdick

Columbia Univ.:

Chmn.—Carter Goodrich
Dean—Philip Young, School of Bus. (AACSB, 1916)

Dir.—C. Wright Mills, Labor Res. Div., Bur. of Applied Soc. Res.

Univ. of Connecticut:

Chmn.—William H. Carter, Jr.
Dir.—Myron H. Clark, Labor-mgt. Inst. (1946)

Cornell Univ.:

Chmn.—Frank A. Southard, Jr.
Dean—Paul M. O'Leary, School of Bus. and Pub. Admin.
Dir.—Milton R. Konvitz, School of Indus. and Labor Rela. (1945)

Creighton Univ.:

Chmn.—Lawrence A. Cusack
Dean—Floyd E. Walsh, Col. of Com.

Dalhousie Univ.: Dir.—L. Richter, Maritime Bur. of Indus. Rela. (1936)

Dartmouth Col.:

Chmn.—William A. Carter
Dean—Herluf V. Olsen, Amos Tuck School of Bus. Admin. (AACSB, 1916)

Davidson Col.: Dean—Cecil K. Brown, Faculty

Univ. of Dayton: Chmn.—Edmund B. O'Leary

Denison Univ.: Chmn.—Leland J. Gordon

Univ. of Denver:

Dean—Cecil Puckett, Col. of Bus. Admin. (AACSB, 1923)

Dir.—Fitzhugh L. Carmichael, Bur. of Bus. and Soc. Res.

Dir.—Alonzo B. May, Teaching Inst. of Econ. (Alfred P. Sloan Found.)

Dir.—Theodore H. Cutler, Bur. of Indus. Rela. (1946)

Chmn.—Frederick W. Mueller, Jr., Col. of Com.

Dean—Father Edward J. Kammer, Col. of Com.

DePaul Univ.: Chmn.—Hiram L. Jome

Univ. of Detroit:

Chmn.—Bernard F. Landuyt
Dean—Lloyd E. Fitzgerald, Col. of Com. and Fin.

Drake Univ.: Chmn.—William E. Alley

Duke Univ.: Chmn.—Calvin B. Hoover

Emory Univ.: Dean—Charles G. Siefkin, School of Bus. Admin.

Fenn Col.:

Chmn.—Clyde J. Crobaugh
John G. McGrew

Univ. of Florida:

Chmn.—Frank W. Tuttle
Dean—Walter J. Matherly, Col. of Bus. Admin. (AACSB, 1929)

Fordham Univ.:

Chmn.—Maurice I. Hart
Dean—William G. Griffith, School of Bus. (AACSB, 1939)

Franklin and Marshall Col.: Chmn.—Horace R. Barner

George Peabody Col. for Teachers: Chmn.—James E. Ward

Georgetown Univ.: Chmn.—Josef Solterer

George Washington Univ.: Chmn.—Donald S. Watson

Univ. of Georgia:

Dean—James E. Gates, Col. of Bus. Admin. (AACSB, 1926)

Dir.—William T. Hicks, Bur. of Bus. Res.

Gonzaga Univ.: Dean—Clifford A. Carroll, School of Bus. and Econ.

Goucher Col.: Chmn.—Elinor Pancoast

Harvard Univ.:

Chmn.—Harold H. Burbank
Dean—Donald K. David, Grad. School of Bus. Admin. (AACSB, 1916)

Haverford Col.: Chmn.—Howard M. Teaf, Jr.

Hofstra Col.: Chmn.—Henry II. Villard

Howard Col.: Rector—Roemilt Hardin

Hunter Col. of City of N. Y.: Chmn.—Nathan Reich

Univ. of Idaho: Chmn.—Ralph H. Farmer

Univ. of Illinois:

Chmn.—
Dean—Howard R. Bowen, Col. of Com.
Dir.—Phillips Bradley, Inst. of Labor and Indus. Rela. (1946)

Illinois Inst. of Tech.: Chmn.—Pearce Davis

Illinois Wesleyan Univ.: Chmn.—William T. Beadles

Indiana State Teachers Col.: Chmn.—Waldo F. Mitchell

Indiana Univ.:

Chmn.—Carroll L. Christenson
Dean—Arthur M. Weimer, School of Bus. (AACSB, 1921)

Iowa State Col.: Chmn.—William G. Murray

Iowa State Univ.: Dean—Chester A. Phillips, Col. of Com. (AACSB, 1923)

James Milkin Univ.: Chmn.—Charles Leese

Johns Hopkins Univ.: Chmn.—George H. Evans, Jr.

Univ. of Kansas: Dean—Leonard H. Axe, School of Bus. (AACSB, 1925)

Kent State Univ.: Chmn.—Hersel W. Hudson

Univ. of Kentucky: Dean—Cecil C. Carpenter, Col. of Com. (AACSB, 1926)

Lafayette Col.: Chmn.—Morrison Handsaker

Laval Univ.: Dir.—Gerald Tremblay, Dept. of Indus. Rela. (1946)

Lehigh Univ.:

Chmn.—Herbert M. Diamond
Dean—Neil Carothers, Col. of Bus. Admin. (AACSB, 1938)

Louisiana State Univ.:

Chmn.—Harlan L. McCracken
Dean—James B. Trant, Col. of Com. (AACSB, 1931)

Univ. of Louisiana: Chmn.—Charles W. Williams
Loyola Univ.:

Chmn.—Eneas B. Goodwin
Acting Dean—J. Raymond Sheriff, School of Com.

Macalester Col.: Chmn.—Forrest A. Young

Univ. of Maine: Chmn.—Himy B. Kirshen

Marquette Univ.:

Chmn.—Robert J. Barr
Dean—Thomas F. Divive, The Robert A. Johnston Col. of Bus. Admin. (AACSB, 1928)

Univ. of Maryland:

Chmn.—Carl J. Ratzlaff
Dean—John F. Pyle, Col. of Bus. and Pub. Admin. (AACSB, 1940)

Massachusetts Inst. of Tech.:
Chmn.—R. E. Freeman

Dir.—Douglas McGregor, Indus. Rela. Sec. (1937)

Massachusetts State Col.: Chmn.—Philip L. Gamble

McGill Univ.: Chmn.—Arthur Lermer, Sir George William Col.

McMurray Col. for Women: Chmn.—Constance L. Raymaker

Miami Univ.:

Chmn.—J. Marvin Peterson
Dean—E. M. McCracken, School of Bus. Admin. (AACSB, 1932)

Michigan State Col.: Chmn.—Herman J. Wyarden

Univ. of Michigan:

Chmn.—I(saiah) L(eo) Sharfman
Dean—Russell A. Stevenson, School of Bus. Admin. (AACSB, 1919)

Dir.—John W. Riegel, Bur. of Indus. Rela. (1934)

Middlebury Col.: Chmn.—Harry M. Fife

Mills Col.: Chmn.—Glenn E. Hoover

Millsaps Col.: Chmn.—E. S. Wallace

Univ. of Minnesota:

Dean—Richard L. Kozelka, School of Bus. Admin. (AACSB, 1920)

Dir.—Dale Yoder, Ind. Rela. Center (1944)

Univ. of Mississippi: Dean—Horace B. Brown, Jr., School of Com. and Bus. Admin. (AACSB, 1944)

Univ. of Missouri:

Chmn.—Russell S. Baunder
Dean—William L. Bradshaw, School of Bus. and Pub. Admin. (AACSB, 1926)

Montana State Univ.: Dean—Theodore H. Smith, School of Bus. Admin.

Univ. of Montreal: Dir.—Emile Bouvier, Indus. Rela. Dept. (1942)

Mount Holyoke Col.: Chmn.—Amy Hewes

Univ. of Nebraska:

Chmn.—Clarence E. McNeill
Dean—Earl S. Fullbrook, Col. of Bus. Admin. (AACSB, 1916)

Dir.—Edgar Z. Palmer, Dept. of Bus. Res.

Univ. of New Hampshire: Chmn.—Joseph E. Shafter

New Jersey Col. for Women: Chmn.—Francis W. Hopkins

Univ. of New Mexico:

Chmn.—Julian S. Duncan
Dean—Vernon G. Sorrell, Col. of Bus. Admin.

New School of Social Research:

Chmn.—Hans P. Neisser, Grad. Faculty of Polit. and Soc. Sci.

Dir.—Adolf Lowe, Res., Inst. of World Affairs

New York State Col. for Teachers: Chmn.—Josiah T. Phinney

New York Univ.:

Chmn.—Major B. Foster
Chmn.—Walter E. Spahr, School of Com., Accts., and Fin.

Chmn.—Emanuel Stein
Dean—John T. Madden, School of Com., Accts., and Fin. (AACSB, 1916)

Univ. of North Carolina:

Chmn.—Albert S. Keister, Woman's Col.

Chmn.—John B. Woosley

Dean—Dudley D. Carroll, School of Com.

(AACSB, 1923)

Dir.—Rex S. Winslow, Bur. of Bus. Serv. and Res.

Univ. of North Dakota: Dean—E. T. Towne,

School of Com. (AACSB, 1925)

Northeastern Univ.:

Chmn.—A. Howard Myers

Dean—Roger S. Hamilton, Col. of Bus. Admin.

Northwestern Univ.:

Chmn.—James W. Bell

Dean—Homer B. Vanderblue, School of Com.

(AACSB, 1916)

Univ. of Notre Dame: Chmn.—John H. Sheehan

Oberlin Col.: Chmn.—Harvey A. Wooster

Ohio State Univ.:

Chmn.—John I. Falconer

Dean—Walter C. Weidler, Col. of Com. and Admin. (AACSB, 1916)

Dir.—Viva B. Boothe, Bur. of Bus. Res.

Dir.—Carroll L. Shartle, Personnel Res. Bd. (1945)

Ohio Univ.:

Chmn.—Edwin T. Hellebrandt

Dean—Adolph H. Armbruster, Col. of Com.

Ohio Wesleyan Univ.: Chmn.—Vant W. Kebker

Oklahoma A. and M. Col.: Dean—Raymond D. Thomas, School of Com.

Univ. of Oklahoma:

Chmn.—Ronald B. Shuman

Chmn.—Floyd L. Vaughan

Dean—Arthur B. Adams, School of Bus. Admin.

(AACSB, 1926)

Dir.—Francis R. Cella, Bur. of Bus. Res.

Univ. of Omaha: Chmn.—Roderic B. Crane

Univ. of Oregon:

Chmn.—Calvin Crumbaker

Dean—Victor P. Morris, School of Bus. Admin.

(AACSB, 1923)

Pennsylvania State Col.: Chmn.—Carl W. Hasek

Univ. of Pennsylvania:

Chmn.—Raymond T. Bowman

Chmn.—Paul F. Gemmill, Grad. Group in Econ.

Dean—C. Canby Balderston, Wharton School of Fin. and Com. (AACSB, 1916)

Dir.—Hiram S. Davis, Ind. Res. Dept., Wharton School

Univ. of Pittsburgh:

Chmn.—Raymond F. Blackburn

Dean—Vincent W. Lanfear, School of Bus. Admin. (AACSB, 1916)

Dir.—Jesse P. Watson, Bur. of Bus. Res.

EXHIBIT IV

THE PROFESSION OF ECONOMIST

The brief statement which follows represents an initial effort to describe what an economist is and what he does and what may be expected by those who contemplate the study of economics as a preparation for a career.

The attempt to formulate an explanation of "economist" as a profession was originally prompted by a request to the Association from the office of the National Roster of Scientific and Specialized Personnel (now a branch of the United States Employment Service of the Department of Labor). The first draft submitted by the Secretary was pitched at too high a professional level and was redrafted by the National Roster staff to meet the needs of those seeking vocational information. This version did not meet our approval and we were given an opportunity to make further criticisms and suggestions. The description in its present form owes its character largely to the revisions made by a committee consisting of F. W. Fetter, Fritz Machlup, H. S. Ellis, and your Secretary.

DESCRIPTION OF THE PROFESSION OF ECONOMIST

Occupational Summary

Economists study the whole process through which man makes a living and satisfies his wants for food, shelter, service or amusement, and the conditions favoring or hampering his economic development. This includes where, how and what man produces, how goods and services are distributed and paid for. They study the organization of industries; the labor supply and its use; the commercial banking and credit structure and government finance, both local and national; international trade and how it is financed; the national income and wealth, its production and distribution; the growth and shifts in population; standards of living; the use and conservation of land and natural resources. The objective of economists is to point out what policies and programs in industry or government will aid in the development of an industry or will facilitate the growth of trade and raise the individual's standard of living. Many economists are college teachers, others are in the employ of industry or government serving as statisticians, research analysts or advisors on economic policies and programs.

Economists study in their basic training all branches of economic theory. Some specialize in one or more branches since many of these subjects tend to overlap or merge.

Major Branches

1. *Economic Theory*: The economist specializing in economic theory is familiar with the history of economic institutions and practices, and makes a comparative and analytical examination of past and present systems of economic organization (e.g. feudalism, state socialism, capitalism, etc.) and of the systems of thought underlying these organizations.
2. *Money, Banking, and Finance*: Economists specializing in this branch study the nature and functions of money and banks, the means by which banks create purchasing power, and devices used to regulate amount of bank lending. They study forms of credit and credit instruments, and the relationship of money purchasing power to levels of economic activity. The fiscal economist studies the ways in which government is financed and public funds are spent; the effects of taxation and spending upon business activity as a whole; and plans a distribution of taxes equitable for all elements of the population.
3. *Industry*: The economist specializing in industry studies forms of business organizations, with arrangements for the production and marketing of goods and services and thus studies costs and prices, private investment policies, wholesale or retail trade, business trends, regulation by

government of industrial monopoly and industry generally. The economist may specialize in one or more specific industries, either non-manufacturing, such as forestry, or construction; or manufacturing, such as food, textiles, lumber, paper, iron, steel, petroleum or rubber.

In the transportation and public utilities industries he studies rates, valuations, traffic or use of service, and materials as they affect railways; aviation; water transportation; electric power and gas; highway, bus and truck transportation; radio and radio broadcasting; and wire communications. He also studies the effects of government regulation, consolidations and monopoly, ownership and operation in these industries.

Economists in this field attempt to explain why the national output of goods and services is subject to fluctuations, and to recommend measures for assuring a higher and more stable level of output and employment. They investigate the influence of private investment (production of new plant and equipment), of government spending and taxing, of monopolies, and of wage policies, upon the level of employment. As a guide to future policy, they make estimates of the size of the national output which our country is capable of producing.

4. *International Trade*: The economist specializing in international trade studies the factors determining the movement of goods among nations; trade restrictions, including tariffs, quotas, and exchange controls; the operation of foreign exchange; international investment and the problems of international capital transfer.
5. *Agricultural Economics*: The agricultural economist studies the economic aspects of agriculture, and its relationship to other fields of economics, in particular transportation, money and banking, and international trade. He studies farm management, crop estimating, agricultural credit, marketing of farm production, and commodity exchanges, and their relation to crop production and prices. He also studies the relationship between the

agricultural production and income and the rest of the economy, its tax structure, labor supply, tariff policies and other aspects.

6. *Labor Economics*: The labor economist studies factors affecting the supply, demand, organization, and well-being of labor. He studies wages and hours; industrial versus craft unions; management policies; pensions, insurance, and other welfare matters; labor legislation; labor disputes; conciliation, arbitration; and the effect of labor policies on industry and the national economy.
7. *Socio-Economics*: The economist specializing in this branch studies broad developments as they affect the economic welfare of the country. This includes such subjects as population growth and movements; national income by social group; the occupational distribution of people; the conservation and use of such natural resources as minerals, water power and land; and regional planning.

Functional Activities

The economist may specialize in one or in a combination of any of the following functional activities:

1. Teaching—at the college or university level. He usually but not always engages in part-time research.
2. Research—he conducts research on a full-time basis in government, in business and industrial establishments, in banks, in labor unions and at private research foundations.
3. Management or Administration of industry or government.
4. Technical editing and writing of books, magazines, pamphlets, and newspaper articles.
5. Consulting and advisory work for governments, business and financial institutions, and investors.

Professional Affiliations and Civil Service Status

Membership in a national or local professional organization is no criterion of professional status since such membership is

open to anyone interested in the objectives or activities of the society. Most economists, however, are affiliated with one or more professional societies.

In the Federal Civil Service and in many state or local civil service jurisdictions, a professional job classification or a rating on a civil service register as economist generally indicates the professional status of the economist. Economists may also be classified by civil service as social science analyst, or labor market analyst, labor relations specialist, tax expert.

Educational Qualifications

The professional economist usually possesses an M.A. or Ph.D. in economics. Such a degree is generally required for advancement in colleges and universities. For the higher levels in the government service and in industry, where the Ph.D. is not shown, the equivalent in professional experience and graduate work is usually required. Junior positions in the Federal service are, however, open to those with a bachelor's degree and a major in Economics.

Related Occupations

(a) High school teachers of economics who

may possess a bachelor's degree in economics are classified as *teachers, high school* rather than as professional economists.

- (b) Journalists and radio news commentators usually are interested in economic affairs and express opinions upon economic issues, but they ordinarily are not classified as economists.
- (c) Bankers, bank cashiers, and related banking, insurance and finance occupations are classified under managerial occupations.
- (d) Home economists are classified as such.
- (e) Those engaged in rural rehabilitation, and farm planning and demonstration are usually not classified as economists.

Sources of Employment

Economists are employed for the most part as college and university teachers, and in research and administrative capacities in government and business (banks, investment houses, railroads, public utilities, manufacturing firms). They find employment also with labor unions and private research institutes. Some are self-employed as consultants.

NUMBER TWO

SCIENCE AND IDEOLOGY*

By JOSEPH A. SCHUMPETER

I

A hundred years ago economists were much more pleased with their performance than they are today. But I submit that, if complacency can ever be justified, there is much more reason for being complacent today than there was then or even a quarter of a century ago. As regards command of facts, both statistical and historical, this is so obviously true that I need not insist. And if it be true of our command of facts, it must be true also for all the applied fields that for their advance mainly depend upon fact finding. I must insist, however, on the proposition that our powers of analysis have grown in step with our stock of facts. A new organon of statistical methods has emerged, to some extent by our own efforts, that is bound to mean as much to us as it does to all the sciences, such as biology or experimental psychology, the phenomena of which are given in terms of frequency distributions. In response to this development and in alliance with it, as well as independently, our own box of analytic tools has been greatly enriched: economic theory, in the instrumental sense of the term—in which it means neither the teaching of ultimate ends of policy nor explanatory hypotheses but simply the sum total of our methods of handling facts—has grown quite as much as Marshall and Pareto had foreseen that it would.

If this is not more generally recognized and if it is etiquette with economists—let alone the public—to pass derogatory judgment on the state of our science, this is owing to a number of causes that, though known all too well, should be repeated: a building plot on which old structures are being torn down and new ones erected is not an esthetic thing to behold; moreover, to a most discouraging extent the new structures are being currently discredited by premature attempts at utilitarian application; finally, the building area widens so

*Presidential address delivered at the Sixty-first Annual Meeting of the American Economic Association, Cleveland, Ohio, December 28, 1948.

that it becomes impossible for the individual worker to understand everything that is going on beyond his own small sector. It would indeed be difficult to present in systematic form, as the Smiths, Mills, and Marshalls have been able to do with more or less success, a comprehensive treatise that might display some measure of unity and command all but universal approval. Thus, though the workers in each sector are not at all displeased with how they are getting on themselves, they are quite likely to disapprove of the manner in which those in all the others go about their tasks, or even to deny that these other tasks are worth bothering about at all. This is but natural. Many types of mind are needed to build up the structure of human knowledge, types which never quite understand one another. Science is technique and the more it develops, the more completely does it pass out of the range of comprehension not only of the public but, minus his own chosen specialty, of the research worker himself. More or less, this is so everywhere although greater uniformity of training and greater discipline of endeavor may in physics reduce the tumult to something like order. As everyone knows, however, there is with us another source of confusion and another barrier to advance: most of us, not content with their scientific task, yield to the call of public duty and to their desire to serve their country and their age, and in doing so bring into their work their individual schemes of values and all their policies and politics—the whole of their moral personalities up to their spiritual ambitions.

I am not going to reopen the old discussion on value judgments or about the advocacy of group interests. On the contrary, it is essential for my purpose to emphasize that *in itself* scientific performance does not require us to divest ourselves of our value judgments or to renounce the calling of an advocate of some particular interest. To investigate facts or to develop tools for doing so is one thing; to evaluate them from some moral or cultural standpoint is, *in logic*, another thing, and the two *need* not conflict. Similarly, the advocate of some interest may yet do honest analytic work, and the motive of proving a point for the interest to which he owes allegiance does not in itself prove anything for or against this analytic work: more bluntly, advocacy does not imply lying. It spells indeed misconduct to bend either facts or inferences from facts in order to make them serve either an ideal or an interest. But such misconduct is not necessarily inherent in a worker's arguing from "axiological premises" or in advocacy *per se*.¹ Examples abound in which economists have estab-

¹ The above passage should be clear. But it may be as well to make its meaning more explicit. The misconduct in question consists, as stated, in "bending facts or logic in order to gain a point for either an ideal or an interest" *irrespective of whether a writer*

lished propositions for the implications of which they did not have any sympathy. To mention a single instance: to establish the logical consistency of the conditions (equations) that are descriptive of a socialist economy will seem to most people equivalent to gaining a point for socialism; but it was established by Enrico Barone, a man who, whatever else he may have been, was certainly no sympathizer with socialist ideals or groups.

But there exist in our minds preconceptions about the economic process that are much more dangerous to the cumulative growth of our knowledge and the scientific character of our analytic endeavors because they seem beyond our control in a sense in which value judgments and special pleadings are not. Though mostly allied with these, they deserve to be separated from them and to be discussed independently. We shall call them Ideologies.

II

The word *idéologie* was current in France toward the end of the 18th and in the first decade of the 19th century and meant much the same thing as did the Scottish moral philosophy of the same and an earlier time or as our own social science in that widest acceptance of the term in which it includes psychology. Napoleon imparted a derogatory meaning to it by his sneers at the *idéologues*—doctrinaire dreamers without any sense for the realities of politics. Later on, it was used as it is often used today in order to denote systems of ideas, that is, in a way in which our distinction between ideologies and value judgments is lost. We have nothing to do with these or any other meanings except one that may be most readily introduced by reference to the "historical materialism" of Marx and Engels. According to this doctrine, history is determined by the autonomous evolution of the structure of production: the social and political organization, religions, morals, arts and sciences are mere "ideological superstructures," generated by the economic process.

We neither need nor can go into the merits and demerits of this conception as such² of which only one feature is relevant to our purpose. This feature is the one that has, through various transformations, developed into the sociology of science of the type associated with the

states his preference for the cause for which he argues or not. Independently of this, it may be sound practice to require that everybody should explicitly state his "axiological premises" or the interest for which he means to argue whenever they are not obvious. But this is an additional requirement that should not be confused with ours.

²In particular, its acceptance is no prerequisite of the validity of the argument that is to follow and could have been set forth also in other ways. There are, however, some advantages in starting from a doctrine that is familiar to all and that needs only to be mentioned in order to call up, in the mind of the audience, certain essential notions in a minimum of time.

names of Max Scheler and Karl Mannheim. Roughly up to the middle of the 19th century the evolution of "science" had been looked upon as a purely intellectual process—as a sequence of explorations of the empirically given universe or, as we may also put it, as a process of filiation of discoveries or analytic ideas that went on, though no doubt influencing social history and being influenced by it in many ways, according to a law of its own. Marx was the first to turn this relation of interdependence between "science" and other departments of social history into a relation of dependence of the former on the objective data of the social structure and in particular on the social location of scientific workers that determines their outlook upon reality and hence what they see of it and how they see it. This kind of relativism—which must of course not be confused with any other kind of relativism³—if rigorously carried to its logical consequences spells a new philosophy of science and a new definition of scientific truth. Even for mathematics and logic and still more for physics, the scientific worker's choice of problems and of approaches to them, hence the pattern of an epoch's scientific thought, becomes socially conditioned—which is precisely what we mean when speaking of scientific ideology rather than of the ever more perfect perception of objective scientific truths.

Few will deny, however, that in the cases of logic, mathematics, and physics the influence of ideological bias does not extend beyond that choice of problems and approaches, that is to say, that the sociological interpretation does not, at least for the last two or three centuries, challenge the "objective truth" of the findings. This "objective truth" may be, and currently is being, challenged on other grounds but not on the ground that a given proposition is true only with reference to the social location of the men who formulated it. To some extent at least, this favorable situation may be accounted for by the fact that logic, mathematics, physics and so on deal with experience that is largely invariant to the observer's social location and practically invariant to historical change: for capitalist and proletarian, a falling stone looks alike. The social sciences do not share this advantage. It is possible, or so it seems, to challenge their findings not only on all the grounds on which the propositions of all sciences may be challenged but also on the additional one that they cannot convey more than a writer's class affiliations and that, without reference to such class affiliations, there is no room for the categories of true or false, hence for the conception of "scientific advance" at all. Henceforth we adopt

³I should consider it an insult to the intelligence of my readers to emphasize that in particular this kind of relativism has nothing to do with Einsteinian relativity were it not a fact that there actually are instances of this confusion in the philosophical literature of our time. This has been pointed out to me by Professor Philipp Frank.

the term Ideology or Ideological Bias for this—real or supposed—state of things alone, and our problem is to ascertain the extent to which ideological bias is or has been a factor in the development of what—conceivably—it might be a misnomer to call scientific economics.

In recognizing the ideological element it is possible to go to very different lengths. There are a few writers who have in fact denied that there is such a thing in economics as accumulation of a stock of “correctly” observed facts and “true” propositions. But equally small is the minority who would deny the influence of ideological bias entirely. The majority of economists stand between these extremes: they are ready enough to admit its presence though, like Marx, they find it only in others and never in themselves; but they do not admit that it is an inescapable curse and that it vitiates economics to its core. It is precisely this intermediate position that raises our problem. *For ideologies are not simply lies*; they are truthful statements about what a man thinks he sees. Just as the medieval knight saw himself as he wished to see himself and just as the modern bureaucrat does the same and just as both failed and fail to see whatever may be adduced against their seeing themselves as the defenders of the weak and innocent and the sponsors of the Common Good, so every other social group develops a protective ideology which is nothing if not sincere. *Ex hypothesi* we are not aware of our rationalizations—how then is it possible to recognize and to guard against them?

But let me repeat before I go on: I am speaking of science which is technique that turns out the results which, together with value judgments or preferences, produce recommendations, either individual ones or systems of them—such as the systems of mercantilism, liberalism and so on. I am not speaking of these value judgments and these recommendations themselves. I fully agree with those who maintain that judgments about ultimate values—about the Common Good, for instance—are beyond the scientist’s range except as objects of historical study, that they are ideologies by nature and that the concept of scientific progress can be applied to them only so far as the means may be perfected that are to implement them. I share the conviction that there is no sense in saying that the world of ideas of bourgeois liberalism is “superior” in any relevant sense to the world of ideas of the middle ages, or the world of ideas of socialism to that of bourgeois liberalism. Actually, I further believe that there is no reason other than personal preference for saying that more wisdom or knowledge goes into our policies than went into those of the Tudors or Stuarts or, for that matter, into Charlemagne’s.

III

So soon as we have realized the possibility of ideological bias, it is not difficult to locate it. All we have to do for this purpose is to scrutinize scientific procedure. It starts from the perception of a set of related phenomena which we wish to analyze and ends up—for the time being—with a scientific model in which these phenomena are conceptualized and the relations between them explicitly formulated, either as assumptions or as propositions (theorems). This primitive way of putting it may not satisfy the logician but it is all we need for our hunt for ideological bias. Two things should be observed.

First, that perception of a set of related phenomena is a pre-scientific act. It must be performed in order to give to our minds something to do scientific work on—to indicate an object of research—but it is not scientific in itself. But though prescientific, it is not preanalytic. It does not simply consist in perceiving facts by one or more of our senses. These facts must be recognized as having some meaning or relevance that justifies our interest in them and they must be recognized as related—so that we might separate them from others—which involves some analytic work by our fancy or common sense. This mixture of perceptions and prescientific analysis we shall call the research worker's Vision or Intuition. In practice, of course, we hardly ever start from scratch so that the prescientific act of vision is not entirely our own. We start from the work of our predecessors or contemporaries or else from the ideas that float around us in the public mind. In this case our vision will also contain at least some of the results of previous scientific analysis. However, this compound is still given to us and exists before we start scientific work ourselves.

Second, if I have identified with "model building" the scientific analysis that operates upon the material proffered by the vision, I must add at once that I intend to give the term "model" a very wide meaning. The explicit economic model of our own day and its analoga in other sciences are of course the product of late stages of scientific endeavor. Essentially, however, they do not do anything that is not present in the earliest forms of analytic endeavor which may therefore also be said to have issued, with every individual worker, in primitive, fragmentary, and inefficient models. This work consists in picking out certain facts rather than others, in pinning them down by labeling them, in accumulating further facts in order not only to supplement but in part also to replace those originally fastened upon, in formulating and improving the relations perceived—briefly, in "factual" and "theoretical" research that go on in an endless chain of give and take, the facts suggesting new analytic instruments (theories) and these in turn carrying us toward the recognition of new facts. This is as

true when the object of our interest is an historical report as it is when the object of our interest is to "rationalize" the Schrödinger equation though in any particular instance the task of fact finding or the task of analyzing may so dominate the other as to almost remove it from sight. Schoolmasters may try to make this clearer to their pupils by talking about induction and deduction and even set the one against the other, creating spurious problems thereby. The essential thing, however we may choose to interpret it, is the "endless give and take" between the clear concept and the cogent conclusion on the one hand, and the new fact and the handling of its variability on the other.

Now, so soon as we have performed the miracle of knowing what we cannot know, namely the existence of the ideological bias in ourselves and others, we can trace it to a simple source. This source is in the initial vision of the phenomena we propose to subject to scientific treatment. For this treatment itself is under objective control in the sense that it is always possible to establish whether a given statement, in reference to a given state of knowledge, is provable, refutable, or neither. Of course this does not exclude honest error or dishonest faking. It does not exclude delusions of a wide variety of types. But it does permit the exclusion of that particular kind of delusion which we call ideology because the test involved is indifferent to any ideology. The original vision, on the other hand, is under no such control. There, the elements that will meet the tests of analysis are, by definition, undistinguishable from those that will not or—as we may also put it since we admit that ideologies *may* contain provable truth up to 100 per cent—the original vision *is* ideology by nature and may contain any amount of delusions traceable to a man's social location, to the manner in which he wants to see himself or his class or group and the opponents of his own class or group. This should be extended even to peculiarities of his outlook that are related to his personal tastes and conditions and have no group connotation—there is even an ideology of the mathematical mind as well as an ideology of the mind that is allergic to mathematics.

It may be useful to reformulate our problem before we discuss examples. Since the source of ideology is our pre- and extrascientific vision of the economic process and of what is—causally or teleologically—important in it and since normally this vision is then subjected to scientific treatment, it is being either verified or destroyed by analysis and in either case should vanish *qua* ideology. How far, then, does it fail to disappear as it should? How far does it hold its own in the face of accumulating adverse evidence? And how far does it vitiate our analytic procedure itself so that, in the result, we are still left with knowledge that is impaired by it?

From the outset it is clear that there is a vast expanse of ground on which there should be as little danger of ideological vitiation as there is in physics. A time series of gross investment in manufacturing industry may be good or bad, but whether it is the one or the other is, normally, open to anyone to find out. The Walrasian system *as it stands* may or may not admit of a unique set of solutions but whether it does or not is a matter of exact proof that every qualified person can repeat. Questions like these may not be the most fascinating or practically most urgent ones but they constitute the bulk of what is specifically scientific in our work. And they are in logic although not always in fact neutral to ideology. Moreover, their sphere widens as our understanding of analytic work improves. Time was when economists thought that they were gaining or losing a point for labor if they fought for the labor-quantity and against the marginal-utility theory of value. It can be shown that, so far as ideologically relevant issues are concerned, this makes as little difference as did the replacement of the latter by the indifference-curve approach or the replacement of the indifference curves by a simple consistency postulate (Samuelson). I dare say that there are still some who find something incongruous to their vision in marginal-productivity analysis. Yet it can be shown that the latter's purely formal apparatus is compatible with any vision of economic reality that anyone ever had.⁴

IV

Let us now look for ideological elements in three of the most influential structures of economic thought, the works of Adam Smith, of Marx, and of Keynes.

In Adam Smith's case the interesting thing is not indeed the absence but the harmlessness of ideological bias. I am not referring to his time- and country-bound practical wisdom about *laissez-faire*, free trade, colonies and the like for—it cannot be repeated too often—a man's political preferences and recommendations as such are entirely beyond the range of my remarks or rather they enter this range only so far as the factual and theoretical analysis does that is presented in support of them. I am exclusively referring to this analytical work

⁴ The contrary opinion that is sometimes met with is to be attributed to the simplified versions of the marginal-productivity theory that survive in textbooks and do not take into account all the restrictions to which production functions are subject in real life, especially if they are production functions of going concerns for which a number of technological data are, for the time being, unalterably fixed—just as in elementary mechanics no account is taken of the complications that arise so soon as we drop the simplifying assumption that the masses of bodies are concentrated in a single point. But a marginal-productivity theory that does take account of restrictions which, even in pure competition, prevent factors from being paid according to their marginal productivities is still marginal-productivity theory.

itself—only to his indicatives, not to his imperatives. This being understood, the first question that arises is what kind of ideology we are to attribute to him. Proceeding on the Marxist principle we shall look to his social location, that is, to his personal and ancestral class affiliations and in addition to the class connotation of the influences that may have formed or may have helped to form what we have called his vision. He was a *komo academicus* who became a civil servant. His people were more or less of a similar type: his family, not penniless but neither wealthy, kept up some standard of education and fell in with a well-known group in the Scotland of his day. Above all it did *not* belong to the business class. His general outlook on things social and economic reproduced these data to perfection. He beheld the economic process of his time with a cold critical eye and instinctively looked for mechanical rather than personal factors of explanation—such as division of labor. His attitude to the land-owning and to the capitalist classes was the attitude of the observer from outside and he made it pretty clear that he considered the landlord (the “slothful” landlord who reaps where he has not sown) as an unnecessary, and the capitalist (who hires “industrious people” and provides them with subsistence, raw materials, and tools) as a necessary-evil. The latter necessity was rooted in the virtue of parsimony, eulogy of which evidently came from the bottom of his Scottish soul. Apart from this, his sympathies went wholly to the laborer who “clothes everybody and himself goes in rags.” Add to this the disgust he felt—like all the people in his group—at the inefficiency of the English bureaucracy and at the corruption of the politicians and you have practically all of his ideological vision. While I cannot stay to show how much this explains of the picture he drew, I must emphasize that the other component of this vision, the natural-law philosophy that he imbibed in his formative years, the product of similarly conditioned men, influenced the ideological background from which he wrote in a similar manner—natural freedom of action, the workman’s natural right to the whole product of industry, individualistic rationalism and so on, all this was taught to him ere his critical faculties were developed but there was hardly need to teach him these things for they came “naturally” to him in the air he breathed. But—and this is the really interesting point—all this ideology, however strongly held, really did not much harm to his scientific achievement. Unless we go to him for economic sociology,⁵ we receive from him sound factual and analytic teaching that no doubt carries date but is not open to objection on the score of ideological bias. There is some semiphilosophical foliage of

⁵ Even there, so I have been reminded by Professor E. Hamilton, there is perhaps more to praise than there is to blame.

an ideological nature but it can be removed without injury to his scientific argument. The analysis that supports his qualified free-trade conclusions is not—as it was with some contemporaneous philosophers, such as Morellet—based upon the proposition that by nature a man is free to buy or to sell where he pleases. The statement that the (whole) produce is the natural compensation of labor occurs, but no analytic use is made of it—everywhere the ideology spends itself in phraseology and for the rest recedes before scientific research. In part at least, this was the merit of the man: he was nothing if not responsible; and his sober and perhaps somewhat dry common sense gave him respect for facts and logic. In part it was good fortune: it matters little if his analysis has to be given up as the *psychology* it was meant to be if at the same time it must be retained as a *logical* schema of economic behavior—on closer acquaintance, the *homo economicus* (so far as Adam Smith, the author of the *Moral Sentiments*, can in fact be credited or debited with this conception at all) turns out to be a very harmless man of straw.

Marx was the economist who discovered ideology for us and who understood its nature. Fifty years before Freud, this was a performance of the first order. But, strange to relate, he was entirely blind to its dangers so far as he himself was concerned. Only other people, the bourgeois economists and the utopian socialists, were victims of ideology. At the same time, the ideological character of his premises and the ideological bias of his argument are everywhere obvious. Even some of his followers (Mehring, for instance) recognized this. And it is not difficult to describe his ideology. He was a bourgeois radical who had broken away from bourgeois radicalism. He was formed by German philosophy and did not feel himself to be a professional economist until the end of the 1840's. But by that time, that is to say, *before* his serious analytic work had begun, his vision of the capitalist process had become set and his scientific work was to implement, not to correct it. It was not original with him. It pervaded the radical circles of Paris and may be traced back to a number of 18th century writers, such as Linguet.⁶ History conceived as the struggle between classes that are defined as *haves* and *havenots*, with exploitation of the one by the other, ever increasing wealth among ever fewer *haves* and ever increasing misery and degradation among the *havenots*, moving with inexorable necessity toward spectacular explosion, this was the vision then conceived with passionate energy and to be worked up, like a raw material is being worked up, by means of the scientific tools of his time. This vision implies a number of statements that will

⁶ See especially S. N. H. Linguet, *La théorie des Lois Civiles* (1767), and Marx's comments on him in Volume I, pp. 77 *et seq.* of the *Theorien über den Mehrwert*.

not stand the test of analytic controls. And, in fact, as his analytic work matured, Marx not only elaborated many pieces of scientific analysis that were neutral to that vision but also some that did not agree with it well—for instance, he got over the kind of underconsumption and the kind of overproduction theories of crises which he seems to have accepted at first and traces of which—to puzzle interpreters—remained in his writings throughout. Other results of his analysis he introduced by means of the device of retaining the original—ideological—statement as an “absolute” (*i.e.*, abstract) law while admitting the existence of counteracting forces which accounted for deviating phenomena in real life. Some parts of the vision, finally, took refuge in vituperative phraseology that does not affect the scientific elements in an argument. For instance, whether right or wrong, his exploitation theory of “surplus” value was a genuine piece of theoretical analysis. But all the glowing phrases about exploitation could have been attached just as well to other theories, Böhm-Bawerk’s among them: imagine Böhm-Bawerk in Marx’s skin, what could have been easier for him than to pour out the vials of his wrath on the infernal practice of robbing labor by means of deducting from its product a time discount?

But some elements of his original vision—in particular the increasing misery of the masses which was what was to goad them into the final revolution—that were untenable were at the same time indispensable for him. They were too closely linked to the innermost meaning of his message, too deeply rooted in the very meaning of his life, to be ever discarded. Moreover, they were what appealed to followers and what called forth their fervent allegiance. It was they which explain the organizing effect—the party-creating effect—of what without them would have been stale and lifeless. And so we behold in this case the victory of ideology over analysis: all the consequences of a vision that turns into a social creed and thereby renders analysis sterile.

Keynes’ vision—the source of all that has been and is more or less definitely identified as Keynesianism—appeared first in a few thoughtful paragraphs in the introduction to the *Consequences of the Peace* (1920). These paragraphs created *modern* stagnationism—stagnationist moods had been voiced, at intervals, by many economists before, from *Britannia Languens* on (1680)—and indicate its essential features, the features of mature and arteriosclerotic capitalist society that tries to save more than its declining opportunities for investment can absorb. This vision never vanished again—we get another glimpse of it in the tract on *Monetary Reform* and elsewhere but, other problems absorbing Keynes’ attention during the 1920’s, it was not implemented analytically until much later. D. H. Robertson in his *Banking Policy*

and the Price Level presented some work that amounted to partial implementation of the idea of abortive saving. But with Keynes this idea remained a side issue even in the *Treatise on Money*. Perhaps it was the shock imparted by the world crisis which definitely broke the bonds that prevented him from fully verbalizing himself. Certainly it was the shock imparted by the world crisis which created the public for a message of this kind.

Again it was the ideology—the vision of decaying capitalism that located (*saw*) the cause of the decay in one out of a large number of features of latter-day society—which appealed and won the day, and not the analytic implementation by the book of 1936 which, by itself and without the protection it found in the wide appeal of the ideology, would have suffered much more from the criticisms that were directed against it almost at once. Still, the conceptual apparatus was the work not only of a brilliant but also of a mature mind—of a Marshallian who was one of the three men who had shared the sage's mantle between them. Throughout the 1920's Keynes was and felt himself to be a Marshallian and even though he later on renounced his allegiance dramatically, he never deviated from the Marshallian line more than was strictly necessary in order to make his point. He continued to be what he had become by 1914, a master of the theorist's craft, and he was thus able to provide his vision with an armour that prevented many of his followers from seeing the ideological element at all. Of course this now expedites the absorption of Keynes' contribution into the current stream of analytic work. There are no really new principles to absorb. The ideology of underemployment equilibrium and of non-spending—which is a better term to use than saving—is readily seen to be embodied in a few restrictive assumptions that emphasize certain (real or supposed) facts. With these everyone can deal as he thinks fit and for the rest he can continue his way. This reduces Keynesian controversies to the level of technical science. Lacking institutional support, the "creed" has petered out with the situation that had made it convincing. Even the most stalwart McCullochs of our day are bound to drift into one of those positions of which it is hard to say whether they involve renunciation, reinterpretation, or misunderstanding of the original message.

V

Our examples might suggest that analytically uncontrolled ideas play their role exclusively in the realm of those broad conceptions of the economic process as a whole that constitute the background from which analytic effort sets out and of which we never succeed in fully mastering more than segments. This is of course true to some extent—

the bulk of our research work deals with particulars that give less scope to mere vision and are more strictly controlled by objective tests—but not wholly so. Take, for instance, the theory of saving which does appear in a wider context in the Keynesian system but might also, factually and theoretically, be treated by itself. From the time of Turgot and Smith—in fact from still earlier times—to the time of Keynes all the major propositions about its nature and effects have, by slow accretion, been assembled so that, in the light of the richer supply of facts we command today, there should be little room left for difference of opinion. It should be easy to draw up a summarizing (though perhaps not very exciting) analysis that the large majority of professional economists might accept as a matter of course. But there is, and always has been, eulogistic or vituperative preaching on the subject that, assisted by terminological tricks such as the confusion between saving and nonspending, has succeeded in producing a sham antagonism between the writers on the subject. Much emphasized differences in doctrine for which there is no factual or analytical basis always indicate, though in themselves they do not prove, the presence of ideological bias on one side or on both—which in this case hails from two different attitudes to the bourgeois scheme of life.

Another instance of sectional ideology of this kind is afforded by the attitude of many, if not most economists, toward anything in any way connected with monopoly (oligopoly) and cooperative price setting (collusion). This attitude has not changed since Aristotle and Molina although it has acquired a partially new meaning under the conditions of modern industry. Now as then, a majority of economists would subscribe to Molina's dictum: *monopolium est injustum et rei publicae injuriosum*. But it is not this value judgment which is relevant to my argument—one may dislike modern largest-scale business exactly as one may dislike many other features of modern civilization—but the analysis that leads up to it and the ideological influence that this analysis displays. Anyone who has read Marshall's *Principles*, still more anyone who has also read his *Industry and Trade*, should know that among the innumerable patterns that are covered by those terms there are many of which benefit and not injury to economic efficiency and the consumers' interest ought to be predicated. More modern analysis permits to show still more clearly that no sweeping or unqualified statement can be true for all of them; and that the mere facts of size, single-sellership, discrimination, and cooperative price setting are in themselves inadequate for asserting that the resulting performance is, in any relevant sense of the word, inferior to the one which could be expected under pure competition in conditions attainable under pure competition—in other words, that economic

analysis offers no material in support of *indiscriminate* "trust busting" and that such material must be looked for in the particular circumstances of each individual case. Nevertheless, many economists support such *indiscriminate* "trust busting" and the interesting point is that enthusiastic sponsors of the private-enterprise system are particularly prominent among them. Theirs is the ideology of a capitalist economy that would fill its social functions admirably by virtue of the magic wand of pure competition were it not for the monster of monopoly or oligopoly that casts a shadow on an otherwise bright scene. No argument avails about the performance of largest-scale business, about the inevitability of its emergence, about the social costs involved in destroying existing structures, about the futility of the hallowed ideal of pure competition—or in fact ever elicits any response other than most obviously sincere indignation.

Even as thus extended, our examples, while illustrating well enough what ideology is, are quite inadequate to give us an idea of the range of its influence. The influence shows nowhere more strongly than in economic history which displays the traces of ideological premises so clearly, precisely because they are rarely formulated in so many words, hence rarely challenged—the subject of the role that is to be attributed in economic development to the initiative of governments, policies, and politics affords an excellent instance: groupwise, economic historians have systematically over- or understated the importance of this initiative in a manner that points unequivocally to prescientific convictions. Even statistical inference loses the objectivity that should in good logic characterize it whenever ideologically relevant issues are at stake.⁷ And some of the sociological, psychological, anthropological, biological waters that wash our shores are so vitiated by ideological bias that, beholding the state of things in parts of those fields, the economist might sometimes derive solace from comparison. Had we time, we could everywhere observe the same phenomenon: that ideologies crystallize, that they become creeds which for the time being are impervious to argument; that they find defenders whose very souls go into the fight for them.

There is little comfort in postulating, as has been done sometimes, the existence of detached minds that are immune to ideological bias and *ex hypothesi* able to overcome it. Such minds may actually exist

⁷ I am not aware of any instances in which the rules of inference themselves have been ideologically distorted. All the more frequent are instances in which the rigor of tests is relaxed or tightened according to the ideological appeal of the proposition under discussion. Since acceptance or rejection of a given statistical result always involves some risk of being wrong, mere variation in willingness to incur such a risk will suffice, even apart from other reasons, to produce that well-known situation in which two statistical economists draw opposite inferences from the same figures.

and it is in fact easy to see that certain social groups are further removed than are others from those ranges of social life in which ideologies acquire additional vigor in economic or political conflict. But though they may be relatively free from the ideologies of the practitioners, they develop not less distorting ideologies of their own. There is more comfort in the observation that no economic ideology lasts forever and that, with a likelihood that approximates certainty, we eventually grow out of each. This follows not only from the fact that social patterns change and that hence every economic ideology is bound to wither but also from the relation that ideology bears to that prescientific cognitive act which we have called vision. Since this act induces fact finding and analysis and since these tend to destroy whatever will not stand their tests, no economic ideology could survive indefinitely even in a stationary social world. As time wears on and these tests are being perfected, they do their work more quickly and more effectively. But this still leaves us with the result that some ideology will always be with us and so, I feel convinced, it will.

But this is no misfortune. It is pertinent to remember another aspect of the relation between ideology and vision. That prescientific cognitive act which is the source of our ideologies is also the prerequisite of our scientific work. No new departure in any science is possible without it. Through it we acquire new material for our scientific endeavors and something to formulate, to defend, to attack. Our stock of facts and tools grows and rejuvenates itself in the process. And so—though we proceed slowly because of our ideologies, we might not proceed at all without them.

BENTHAM AND J. S. MILL: THE UTILITARIAN BACKGROUND*

By JACOB VINER

The one-hundredth anniversary of the publication of J. S. Mill's *Principles of Political Economy* falls in the year 1948, and the American Economic Association in the programming of its meetings takes advantage of anniversaries of births, deaths, and dates of publication to remind its members that our discipline has a past. This is a proper occasion, therefore, for a paper on J. S. Mill. The inclusion of Bentham in the scope of my paper is of my own contriving, but perhaps I can technically legitimize it by appeal to the fact that British learned circles have been celebrating during 1948 the two-hundredth anniversary of Bentham's birth. There is no intellectual difficulty, however, in associating Bentham with Mill. The intellectual history of Mill is in large part a history, first, of faithful discipleship, then of rebellion from, and finally of substantial return, to the Benthamite set of doctrines.

The general lines of Bentham's thought were wholly of the eighteenth century, as I could demonstrate if there were time. Of English intellectuals who have had great influence, Bentham was perhaps the least original in his stock of general ideas, but clearly the most original in finding means and devices for putting his philosophy to practical use. To the nineteenth century Bentham was important as a carrier of eighteenth century thought and, still more, as a translator of this thought into a program of social reform. It was the seventeenth century which was the Age of Genius. The philosophers of the eighteenth century were, nonetheless, fertile in ideas. They were, however, almost completely devoid of zeal for the application of these ideas to change of institutions, or even of zeal in generating ideas which would call for change in existing institutions.

We economists like to think of Adam Smith as an exception in this regard, but he was so only to a moderate extent. The one social issue on which Adam Smith was a zealot was the issue of freedom of trade *versus* mercantilism. But Smith had little confidence in the ability of ideas to move worlds. It is often overlooked that it was with reference to internal and not to international free trade that Adam

*This paper was presented at the meetings of the American Economic Association, December 29, 1948.

Smith made his famous statement that "To expect, indeed, that the freedom of trade should ever be entirely restored in Great Britain, is as absurd as to expect that an Oceana or Utopia should ever be established in it," and this although when he wrote, by obsolescence rather than by deliberate repeal, the restrictions on internal freedom of trade had already become largely inoperative. There is no evidence that Smith was more optimistic about the prospects for international than for domestic free trade, or that, beyond writing his book and preparing a few memoranda for the government when called upon, he ever felt moved to do anything, and especially to resort to anything rude or, in the eighteenth-century meaning of the term, to "enthusiasm," to obtain acceptance and execution of his reforming ideas.

The eighteenth century, in Britain if not in France, and before the American and the French Revolutions if not after, was the age of social complacency, political, economic, moral, of satisfaction with the *status quo* at least to the extent of belief that the costs of substantial change would exceed the benefits of removal or moderation of whatever evils were recognized to prevail. British eighteenth-century government was oligarchic, corrupt, inefficient, though it was generally not tyrannical in intent and usually too lax, too inert, too decentralized, and too sceptical to be seriously tyrannical in effect. Until the end of the century there was no major figure who even mildly suggested the need for major political reform. Whether the economic condition of the masses of the people was improving or deteriorating, and whatever its trend, whether it was desperately bad or moderately good as compared to later standards, I frankly have no idea. We may rest assured, however, that it was not idyllic, if only because it never is.

Nevertheless, there was not until the very last moments of the century either a single major political debate which turned on the economic conditions of the poor or a single major writer who had important suggestions as to how to improve them, with the sole exception of Adam Smith's plea for freedom of trade. It was even a common doctrine of the century that the poor should never be relieved of their poverty above the level of a bare subsistence plus perhaps a few crumbs of cake, and it was at least the quasi-official doctrine of the Church of England that the poverty of the poor—and the prosperity of the bishops—were in accordance with the Divine Will.

Bentham and the Benthamites, on the other hand, were never complacent about the condition of the people of England. They were "Radical Reformers," and they worked hard at their reforms: by working out detailed blueprints for them; by propaganda, agitation, intrigue, conspiracy; and, if truth be told, by encouragement to revolutionary movements up to—but not beyond—the point where resort to physical

force would be the next step. Bentham, moreover, was a successful social reformer, more successful perhaps than anyone else in history except Karl Marx—I have in mind here only the realization and not the merits of programs of change—if he is given credit for those changes which came after his death as the result largely of the efforts of his disciples.

The list of reforms in England which derive largely from Bentham is a truly impressive one, and I present it here only in part: fundamental law reform in many of its branches; prison reform; adult popular suffrage, including woman suffrage; free trade; reform in colonial government; legalization of trade unions; general education at public expense; free speech and free press; the secret ballot; a civil service appointed and promoted on merit; repeal of the usury laws; general registration of titles to property; reform of local government; a safety code for merchant shipping; sanitary reform and preventive medicine at public expense; systematic collection of statistics; free justice for the poor. Bentham was the first person to propose birth-control as a measure of economic reform, and this *before* Malthus had published his first *Essay on the Principle of Population*.¹ The Ministry of Health which he proposed would be made responsible not only for general sanitation and routine public health work, but also for smoke prevention, local health-museums, and the policing of the medical profession to prevent their formation of monopolies. ✓

Related to the conditions of the time when these reforms were proposed, Bentham's program was comprehensive, radical, and progressive without being visionary. The modern "democratic socialist" would find it wanting, since Bentham did not approve of tampering with the system of private property except through inheritance taxation and insisted on "compensation" where reform measures would involve violation of "reasonable expectations." He apparently never formulated any concrete proposals for social security on an insurance basis, but he approved in principle of government-administered and government-subsidized insurance against every conceivable type of social hazard for which individual prudence could not make adequate provision. It was too early for proposals to stabilize employment through monetary or fiscal measures, although Bentham did explore the possibility of increasing real investment and production through the "forced frugality" induced by the issue of paper money.² Pronounced in-

¹ See J. Bentham, "Situation and Relief of the Poor," *Annals of Agriculture*, Vol. XXIX (1797), pp. 422-23 (p. 31, in the separate pamphlet version). See also Norman E. Himes, "Jeremy Bentham and the Genesis of English Neo-Malthusianism," *Economic History* (Suppl. of *The Economic Journal*), Vol. III (1936), pp. 267-76.

² Bentham's treatment of this still remains in large part in manuscript. Extracts from these unpublished manuscripts and comments by Ricardo on them have recently been

dividualist though he was, his specific program of reforms in both the content and the processes of legislation, in governmental organization, and in public administration, made him a major source of inspiration for the Fabian socialists as well as for the laissez-faire liberals.

To belief in political democracy Bentham came only slowly, and only as their failure to adopt his proposals eroded his faith in the good intentions of the British aristocratic politicians. The Benthamite case for political democracy was first elaborately expounded by James Mill in his famous essay on Government first published in 1820. It turned out to be an embarrassment for Bentham and his other disciples because by the scholastic formalism of its argument and the extreme lengths to which it carried Bentham's doctrine it was seriously vulnerable to rebuttal and, even worse, to ridicule. Starting out from the proposition that the sole proper purpose of government is to promote the greatest happiness of mankind, James Mill proceeded by purely *a priori* analysis, without any reference to history or to contemporary fact, from the premise that legislators served *only* their "sinister interests"—a stock Benthamite term for the self-interest of rulers or a ruling class—to the conclusion that good government was therefore obtainable only by making it, through popular suffrage and frequent elections, the self-interest of the elected to serve the interests of the electors.

Bentham, writing in the 1780's, had conceded that if at any time legislators "have suffered the nation to be preyed upon by swarms of idle pensioners, or useless place-men, it has rather been from negligence and imbecility, than from any settled plan for oppressing and plundering of the people," but in 1814 he appended a note withdrawing the concession: "So thought Anno 1780 and 1790.—Not so Anno 1814.—J. Bentham."³ By that time he had adopted the doctrine of "Sinister Interests." But James Mill carried the doctrine further than was necessary to meet Bentham's requirements and probably further than Bentham's belief in it. As Tawney has remarked: "To [James Mill] the State is not a band of brothers, but a mutual detective society; the principal advantage of popular government is that there are more detectives, and therefore, presumably, fewer thieves."⁴ Bentham always, but James Mill rarely, if ever, conceded that men, even legislators, could not only be influenced by the praise and blame of other men,

published by Edmund Silberner, "Un Manuscrit Inédit de David Ricardo sur le Problème Monétaire," *Revue d'Histoire Économique et Sociale*, Vol. XXV (1940), 195-259, and were then also already in page proof in Piero Sraffa's long-forthcoming edition of Ricardo's works.

³ Bentham, "Principles of Morals and Legislation," *Works* (Edinburgh, 1838-1843), I. 5.

⁴ R. H. Tawney, preface to *Life and Struggles of William Lovett*, new ed. (New York, 1920), p. xxi.

but could even display some measure of pure benevolence. As Barker has commented: "... while all—or nearly all—of the theorems of Mill's article may be found in Bentham, they have undergone a change. The egoism is more egoistic; the negativism is more negative,"⁵ and it may be added the *a priori* analysis more "high *priori*." In the seventeenth century Harrington had denied that Hobbes could work the miracle of "making you a king by geometry." Macaulay was now to deny that the Benthamites could depose an aristocracy by geometry.

Macaulay, a young man anxiously seeking fame by his fluent and facile pen, found the opportunity in James Mill's essay on Government. Reviewing in 1829, in the magisterial *Edinburgh Review*, a reprint of this essay of James Mill, Macaulay raked it high and low, primarily on the basis of its use, without benefit of historical induction or of reference to contemporary facts, of the *a priori* or, in the language of the time and earlier, the geometrical method, but also on the more concrete ground that the proposition that legislators *always* and *invariably* act in terms of their selfish interests was preposterous whatever the method by which it was attempted to establish it.⁶

The Benthamites were shaken by the attack, and J. S. Mill most so, as we shall see later. But Macaulay himself, without withdrawing anything of what he had written, soon thereafter made his peace with James Mill and from then on was an exponent of political democracy on the basis of a line of argument which Paxton in his *Civil Polity* had already presented in 1703, and which should have been the original and was to become the standard line of the Benthamites, namely, that only by democratic voting could there be an adequate guarantee that legislators would *always* or predominantly serve the general interest, without denial that they might sometimes do so even in the absence of democracy.

I come now to deal more systematically with the most difficult and the most controverted aspect of Benthamism, namely, its psychological and ethical justifications for utilitarianism as legislative policy.

Bentham's main concern with ethics was with the ethics which should be followed by moral leaders, not with the ethics of the ordinary man, not with private morals, except as they were data to be operated on by the elite. "The science," he said, "whose foundations we have explored can appeal only to lofty minds with whom the public welfare has become a passion."⁷ And by them, Bentham held, its lessons should be pressed on legislators, whether *their* minds were lofty ones or not.

⁵ Sir Ernest Barker, in the preface of his edition of James Mill, *Essay on Government* (Cambridge, England, 1937).

⁶ See the preface, pp. ix-xi and pp. 160 ff. of *The Miscellaneous Writings and Speeches of Lord Macaulay*, Popular Edition (London, 1891).

⁷ *Theory of Legislation*, C. M. Atkinson ed. (London, 1914), II. 337.

As Bentham acknowledged,⁸ he sometimes overlooked this, and wrote as if what he had to say was directed at private morals, and critics have made much of this oversight without treating it merely as a lapse from his fundamental purposes. It was Benthamism interpreted as a system of private ethics, didactic as well as descriptive, that has aroused the most violent and the most emotional antagonism. Even as private ethics, however, Benthamism has seemed so vulnerable a target to *odium theologicum* and *odium ethicum* only because the private ethics of the critics permitted them to attack Bentham's words without taking pains to ascertain what the thoughts were which these words were intended to communicate.

Bentham starts from the standard eighteenth-century proposition, common to theologians and to sceptical philosophers alike, that man operates "under the governance of two sovereign masters, pain and pleasure." Happiness is a net sum or aggregate of individually experienced pleasures and pains.⁹ Man, he claims, acts only in response to his "interests," by which he usually, and fundamentally, means whatever men are interested in, but, unfortunately, frequently allows to mean what men regard as in their self-interest. Men normally are interested to some extent in the happiness of others than themselves, and in exceptional cases are capable of "universal benevolence," or a dominating concern with the happiness of mankind at large, but generally, if they are left to themselves, there will be serious discrepancy between the actual behavior of individuals and the behavior which would conduce to "the greatest happiness of the greatest number." It is the function of legislation to coerce or bribe individuals to make their behavior coincide with that required by the greatest-happiness principle, and of education and moral leaders to mould men's desires so that they spontaneously associate the happiness of others with their own happiness.

Bentham nowhere attempts or asserts the possibility of a positive demonstration that greatest happiness, whether as hedonism or as eudaemonism, is the proper moral objective for the common man, the moral leader, or the legislator, and his only argument in support of the greatest-happiness principle is the negative one that the rival principles proposed by other ethical systems are either resolvable upon scrutiny to verbal variants of the utility principle, or are sheer *ipse dixitism*, or are meaningless patterns of words.

⁸ Cf. for example, the preface, first added to the 1823 edition, of his *Introduction to the Principles of Morals and Legislation*, where he says that "an introduction to a penal code" would have been a title better indicating the nature of its contents.

⁹ Cf. "Gamaliel Smith" [=Jeremy Bentham], *Not Paul, but Jesus* (London, 1823), p. 394: "happiness, to be anything, must be composed of pleasures: and, be the man who he may, of what it is that gives pleasure to him, he alone can be judge."

"Pleasure" and "happiness" were to Bentham widely inclusive terms, involving not only the pleasures of the senses but also those of the heart and the mind. Pleasures, moreover, which in their "simple" or primary form, genetically speaking, were pleasures of self could by "association of ideas" become associated with the pleasures of others. Man, by living in society, by education, and by acts of parliament, could be made good. The eighteenth-century utilitarians may have traded, as a German philosopher has put it, "in the small wares of usefulness (*Nutzlichkeitskrämerei*)."¹⁰ Or it may be that to accept the pursuit of pleasure as a proper end of man is "swinish doctrine," if it be proper to assume that man pursues swinish pleasures. But a utilitarian does not have to be a Philistine. If in Bentham's exposition of his psychology there was often undue stress on the selfish sentiments, this fault—which was much more evident in James Mill than in Bentham—was the result of lack of imagination and of feeling, or of faulty observation—itsself the consequence of these lacks—rather than any inherent incompatibility of broader views with the logic of his system. One important manifestation of this—systematic on the part of James Mill but only occasional and incidental on the part of Bentham—was the assumption that even when one's own pleasure had through association of ideas become involved in the pleasure of other persons, the affectionate sentiments toward others still contained an element of conscious reference back to one's own pleasures. This, by implication at least, was a proclamation of the universal prevalence of psychological hedonism.¹⁰

The eighteenth century is often termed the "Age of Reason," and it is correctly so termed if by the phrase is meant that it was the age in which philosophers held that the credibility of all things should be tested by reason. But from the point of view of its prevailing psychological doctrines, it could more properly be called the "Age of the Passions" because of its stress on the emotions and the instincts, the affections and aversions, and its playing down of the role of reason in the behavior of the ordinary man. David Hume was writing in the spirit of his times when he declared that: "Reason is and ought only to be the slave of the passions, and can never pretend to any other office than to serve and obey them." The normal role of reason was that of an obedient servant of the passions, a passive agent for the comparison of their relative intensities and for the justification of the choices made between them. "So convenient a thing," said Bentham in his Autobiography, "it is to be a reasonable creature, since it enables

¹⁰ In notes to his edition of James Mill, *Analysis of the Phenomena of the Human Mind* (London, 1869), J. S. Mill, without fully admitting that his father had held this doctrine, points out passages which could be interpreted as implying it. See II. 217, note; II. 224, note; II. 286 ff. note, etc.

one to find or make a reason for everything one has a mind to do."

For the moral philosopher and the properly conditioned legislator, however, Bentham assigned more important roles to reason, first, that of moulding the passions of individuals so that they would contribute more to the augmentation of general happiness, and second, that of providing a technique for the comparison of passions of individuals with a view to making a socially oriented choice between them where choice had to be or could be made. It was for this social purpose, and not for the routine behavior of routine individuals, that Bentham endeavored to construct what he at different times labelled as a "moral thermometer," a "moral arithmetic," a "felicific calculus."

Much amusement has been derived from Bentham's attempt to develop a technique by which the quantities of pleasure and pain could be measured by the legislator or the benevolent philosopher. Wesley Mitchell's well-known essay on "Bentham's Felicific Calculus,"¹¹ is the fullest and the least unsympathetic account I am acquainted with of Bentham's position on this question. Mitchell points out the excessive degree of hedonism attributed by Bentham to mankind, and comments penetratingly on Bentham's attempt to find a common denominator through money for the pleasures of different persons. Mitchell says that in fact Bentham used the calculus not as an instrument of calculation, but as a basis of ordinal classification. "It pointed out to him what elements should be considered in a given situation, and among these elements *seriatim* he was often able to make comparisons in terms of greater and less—" I think this is a somewhat misleading description of Bentham's method. The "classification" was not *seriatim*, was not in terms of higher and lower, but merely of pro and con, of pleasure and pain, and was wholly preliminary to rather than part of the calculus. The "calculus" as he actually used it was merely a mental comparison of the comparative weights of the pros and cons, a technique which neither calls for fancy labels nor is properly conducive either to merriment or to measurement.

Bentham did not invent the concept or the terminology of "moral arithmetic." Play with the idea of measuring the unmeasurable and resort to the language of measurement where it was silly to attempt to apply it goes back to at least the seventeenth century, when the prestige of geometry and later of algebra tended to trap all philosophers with scientific pretensions into casting their analysis into pseudo-mathematical form. Mandeville, as early as 1730, laughed at physicians who studied mathematics because it was fashionable, and cited one who had advised that for certain diseases "the doses of the medicines

¹¹ Reprinted in W. C. Mitchell, *The Backward Art of Spending Money* (New York, 1937), pp. 177-202.

are to be as the Squares of the Constitutions."¹² Thomas Reid, in his *Essay on Quantity* of 1748, questioned the possibility of reducing to measurement such things as sensations, beauty, pleasure, and the affections and appetites of the mind, even though they "are capable of more and less," and he warned that to apply mathematical language to non-measurable things "is to make a show of mathematical reasoning, without advancing one step in real knowledge."¹³

Bentham never went far afield for the sources of his ideas, and I suspect that Benjamin Franklin was his source, direct or indirect, for this idea of classification by "bipartition" plus "measurement" of the relative weight of the two classes. Franklin a few years earlier, in 1772, had been expounding it in private correspondence with Joseph Priestley and Richard Price—with all three of whom Bentham had personal contacts—in very much the same terms as Bentham was later to use, and under the similar, and already old, label of "moral or prudential algebra."¹⁴

None of Bentham's immediate disciples showed any interest in this aspect of Bentham's thought, and it was not until Jevons drew attention to it and made it the basis of his subjective theory of economic value that it had any influence, for good or bad. I like to think, more so probably than Wesley Mitchell would have appreciated, that Bentham's felicific calculus was merely one more manifestation of the inferiority complex which practitioners of the social "sciences" had in the eighteenth century, and have reacquired in the twentieth, towards mathematics, towards the exact sciences, and towards quantification as one of the higher virtues. Since with the application of "political arithmetic" to "moral arithmetic" we now all accept without protest the derivation of measured "propensities" from correlations between psychologically and otherwise promiscuous statistical aggregates compiled catch-as-catch-can on anything up to global scale, our readiness to laugh at Bentham's modest and wholly platonic gestures in this direction excites my propensity for amazement.

There remains one question, specially important for economics, where the influence of Bentham on J. S. Mill is obvious, the question of laissez-faire, or the economic role of government. Élie Halévy, in his great but tendentious work on the Benthamites,¹⁵ has made much of the existence in Bentham's system of a conflict between his juristic and

¹² Bernard Mandeville, M.D., *A Treatise of the Hypochondriack and Hysterick Diseases*, 2nd ed. (London, 1730), p. 184. Compare the history of "Lullism."

¹⁴ *The Monthly Repository*, Vol. XII (1817), p. 13, and *Proceedings of the Massachusetts Historical Society*, 2nd ser., Vol. XVII (1903), p. 264.

¹⁵ *La Formation du Radicalisme Philosophique*, 3 vols. (Paris, 1901-1904). There is an inferior edition in English in one volume.

his economic doctrines. According to Halévy, Bentham in his juristic theory makes it the primary function of government to create an *artificial* harmony between the interests of individuals and the public interest, whereas in his economic theory he reaches laissez-faire conclusions on the basis of an implied natural or spontaneous harmony of interests. This has become a stereotype of present-day comments on Bentham, and although there may be exceptions to the natural law which proclaims that stereotypes in the field of the history of ideas provide a light which blinds rather than guides, this is not one of them.

Bentham did interpret the function of government, under the influence largely of Helvétius, as that of creating, through the application of rewards and punishments, an approach to harmony between the interests of individuals and the social interests. He did prescribe limits for the field for governmental intervention in economic matters, but these limits were not, as we shall see, very narrow ones, and in any case were not so narrow as to give scope for a doctrine of natural harmony of interests, in the sense of a harmony preordained or inherent in the nature of man living in a society unregulated by government. Of explicit formulation by Bentham of a doctrine of natural harmony I can find not the slightest trace in his writings, and such a doctrine would be in basic conflict not only with his juristic theories but with his whole cosmological outlook. Faith in natural harmony always stems from either faith in the continuous intervention of a beneficent Author of Nature or faith in the workings of a natural evolutionary process, and the Benthamites rejected the former and had not yet heard of the latter.

It has been common since Adam Smith's day to take for granted *in economics* the role of the state with reference to the protection of legal property rights and the enforcement of contracts, leaving it to juristic inquiry to explore the problems of theory and of practice in this field. Such was also the procedure of Bentham, and in his juristic writings he keeps very much in mind that "passion . . . from the excesses of which, by reason of its strength, constancy, and universality, society has most to apprehend; I mean that which corresponds to the motive of pecuniary interest."¹⁶ Here he deals with the problem of "repression" of harmful economic activity by means of civil and penal law. If Bentham believed that there was a natural harmony of private and public interests in the economic field, it was one, therefore, which would prevail only after the magistrate and the constable had performed their duties.¹⁷

¹⁶ "Introduction to the Principles of Morals and Legislation," *Works*, Vol. I, pp. 90-91.

¹⁷ Bentham deals briefly with the relations between political economy and law in "A General View of a Complete Code of Laws," *Works*, Vol. III, pp. 203-4.

But Bentham does not advocate anything like "anarchy plus the constable." His most general proposition of a laissez-faire character is as follows: ✓

With the view of causing an increase to take place in the mass of national wealth, or with a view to increase of the means either of subsistence or enjoyment, without some special reason, the general rule is, that nothing ought to be done or attempted by Government. The motto, or watchword of Government, on these occasions, ought to be—Be Quiet.¹⁸

This may sound like a sweeping enough support of laissez-faire, if, as is common though rarely desirable practice in such matters, it be read carelessly and out of its context. There are important qualifications, explicit or implied, within this apparently emphatic text. First, the text deals with "encouragement" and not with "repression" of economic activity. As I have already pointed out, Bentham deals with the problem of repression of harmful economic activity as a problem in law and not in economics. Second, the general rule of doing nothing positive is applicable only if there is no special reason to the contrary. A rule is not equivalent for him to a principle, nor a "motto" to a dogma.

Bentham presents three grounds for the general rule against governmental activity of a positive kind in the economic field: (1) in this field, individuals know their own interest better than government can; (2) individuals operate more ardently and more skillfully in pursuit of their own interests than government can or will operate on their behalf; (3) governmental intervention means coercion, either directly or indirectly through taxation, and coercion involves "pain" and therefore is an evil.

Bentham is ready to approve of any departure from the general rule, however, if a case can be made for such departure on utility grounds. "Indiscriminate generalizations" are an error, he says, and "In laying down general rules, [even] fortuitous and transient cases ought not to be forgotten." And he lives up to his doctrine as, for instance, when he says that "what ought not to be done with the intention of supporting an unprofitable branch of trade, may yet be proper for preventing the ruin of the workmen employed in such business," or, when opposing in general any restrictions on the introduction of labor-saving machinery, he approves, however, of transitory aid to workmen injured economically by such introduction.

Bentham does not, moreover, limit his exceptions from the non-intervention rule to fortuitous and transient cases, but presents an elaborate analysis of the circumstances under which government should

¹⁸ "Manual of Political Economy," *Works*, Vol. III, p. 33. All subsequent citations of Bentham are from the "Manual."

not ("non-agenda") and those under which it should ("agenda") intervene. The argument may, to some tastes, be weighted too heavily on the side of *non-agenda*, but it is free from any dogma except the utilitarian one with which it is supposed by Halévy to clash.

Whether government should intervene, says Bentham, should depend on the extent of the power, intelligence, and inclination, and therefore the spontaneous initiative, possessed by the public, and this will vary as between countries. "In Russia, under Peter the Great, the list of *sponte acta* being a blank, that of *agenda* was proportionally abundant." Government has special responsibilities for providing security against food shortages as well as military security. He approves of government aid in the construction of roads, canals, iron railways, of public hospitals for the sick, hurt and helpless, of public establishments for the "occasional maintenance and employment of able-bodied poor," and, as we have seen, of public health activities on a scale still unknown. He was an ardent advocate of general education at public expense and he urged the extension of governmental registration services to make fraud more hazardous—and also of the systematic collection of economic statistics, but with a proviso which I suspect saps his concession of most of its virtue for modern statisticians, namely, that "no institution should be set on foot for the furnishing any such articles, without a previous indication of the benefit derivable from such knowledge, and a conviction that it will pay for the expense." ✓

Whatever its merits or defects, this treatment of the economic role of government is not in manner or substance doctrinaire, is not in any detail, as far as I can see, inconsistent with his general "principle of utility," and does not have in it, explicitly or implicitly, any trace of a doctrine of natural harmony of interests. It is to be borne in mind, moreover, that the best Bentham hopes for after all that can be done artificially to harmonize private interests with the public interest will still be far from perfect harmony. This has, indeed, been made the basis from another point of view of attack by moral philosophers of other faiths against utilitarianism: it is taken to task for failing to build a bridge between individual and general happiness. But this would be a valid criticism only if either it had professed to have succeeded in doing so and failed, or if it were a proper demand of *any* moral philosophy that it should provide a *practicable* scheme of perfect harmony of interests. Bentham did not completely bridge the gulf between private interests and the general interest, but neither did he deny the existence of such a gulf, and he did propose two ways, education and government, by which the gulf could be somewhat narrowed—with religion, though grudgingly, accepted as a useful part of education in so far as it educates for virtue. Does anyone know of a third way?

I turn now to John Stuart Mill. His famous *Autobiography*—revealing, but not as much so as he no doubt intended—made generally known the extraordinary intellectual régime to which he had been subjected as a boy by his father, and the precocity which resulted from it. In 1822, at the age of sixteen, he was engaging the redoubtable Robert Torrens in battle in the pages of an important newspaper about the theory of (economic) value. Before he was twenty he had edited Bentham's three-volumed work on the *Rationale of Evidence*, had published at least seven major articles in important periodicals on economic, political, and legal matters, had pointed out with great assurance and even less reverence the literary, political, economic, philosophical, and ethical shortcomings of the august *Edinburgh Review*, and had been arrested for distributing birth-control pamphlets.

In this first stage of his career, drilled to a rigid adherence to the Benthamite canon, J. S. Mill was a zealous exponent of Bentham's, and of his father's moral and political doctrines and of Ricardo's economics. In 1826, however, when still in his twentieth year, he underwent a mental crisis, which continued intermittently for several years and which brought him sieges of mental depression, as well as an intellectual conversion which he was later, in his *Autobiography*, to describe as akin to a religious "conviction of sin," the sin being in effect Benthamism.

It is conceivable that J. S. Mill's main trouble was primarily due to overwork, but his own explanation was that the sudden realization that the Benthamite doctrines left the nobler human feelings too much out of account and did not offer a sufficiently full prospect for human happiness had proved more than he could take. During these and subsequent years, he manifested the characteristic which was to remain prominent in all the rest of his career, his susceptibility to influence from widely diverse ideas or, as he was later to put it in his *Autobiography*, his "great readiness and eagerness to learn from everybody, and to make room in my opinions for every new acquisition by adjusting the old and the new to one another." New winds of doctrine were impinging on his mind, which was then as open as a prairie: Wordsworth's nature-poetry, with its reverence for beauty and its revelation—for a Benthamite—that there were other fruitful sources of impressions than those provided by syllogisms; the reading of one of Comte's early works and personal associations with Saint-Simonians, which brought him into contact with the new historical approach to social thought; Macaulay's refutation in the *Edinburgh Review* of his father's *a priori* demonstration of the superiority of democracy to aristocratic government; the conservative political views and the more-or-less orthodox religious views of his friends John Sterling and Frederick Maurice; the feudalistic and pre-

fascistic doctrines being expounded with fiery moral passion by Carlyle; and so forth. From all of them he borrowed something, although never as much as he then supposed, and for the most part not for keeps.

For a time, while his dour and magerful father still lived, the younger Mill did not break openly with the Benthamites, but his personal relations with the school became strained—more so, in fact, than he was ever to be aware of. Bentham, however, died in 1832 and James Mill in 1836, and freed from the restraint of their disapproval and evident disappointment, J. S. Mill began to explore the new ground on which he not too firmly stood by the hazardous procedure of putting his thoughts in print for the public to read.

The break was sharpest in the field of private ethics, where Bentham's and James Mill's interest had been least. In his economics, J. S. Mill remained faithful to the Ricardian doctrines as he understood them—and, to some extent, improved upon them in the process of interpreting them. In any case, the Ricardian economics was not wholly acceptable to Bentham, nor Bentham's economics at all acceptable to Ricardo. In the fields of politics and of law, J. S. Mill proclaimed some major departures in his thinking from the views of Bentham, but he never specified what they were. I think that, apart from some wavering as to the virtues of political democracy and some approaches to the benevolent Toryism of Coleridge, Wordsworth, Sterling, and Maurice, these were mainly methodological, loss of faith in the adequacy of the "geometrical" method in politics, rather than substantive.¹⁹ With his father's writings he never, it seems to me, dealt with complete frankness, and he reserved for Bentham blows which could more justly have been directed against James Mill. The harshness and vehemence of the attack on Bentham was no doubt a subconscious manifestation of the urge he was under to free himself from what he had come to feel was an intellectual straitjacket, but it had been his father rather than Bentham who had placed it on him.

The attacks on Benthamism began in 1833, while his father was still living but after Bentham had died, with critical "Remarks on Bentham's Philosophy" included, under cover of anonymity, as an appendix to Bulwer Lytton's *England and the English*. In 1838, or two years after his father's death, he published in the *London and Westminster Review* his famous full-dress article on Bentham, again anonymous, but with the authorship inevitably known at once to friends

¹⁹ For his attempt to substitute, under Saint-Simonian influence, a philosophy-of-history approach, see his series of essays on "The Spirit of the Age," originally published anonymously in the *Examiner* in 1831, and reprinted in 1942 by the University of Chicago Press, with a characteristically learned and penetrating introduction by F. A. Hayek.

and foes. In 1840, he published in the same *Review* an article on Coleridge, which, by its sympathetic treatment of the latter's ethical and political views, was indirectly a criticism of Benthamism.

Meanwhile, in 1835, in a review in the *London and Westminster* of a book by Adam Sedgwick which criticized utilitarian ethics as expounded by Paley, he had defended the principle of utility when properly expounded, but without mentioning any names had remarked that for a full exposition of it additional materials were needed beyond those already to be found in the writings of philosophers.

In these articles Mill was clearly endeavoring to salvage, or at least shrinking from abandoning, a utilitarian system of ethics while rejecting such features of Bentham's system as he could no longer tolerate. There was high praise, therefore, for Bentham as well as sharp blame. His main criticism of Bentham related to his treatment of private morals and of psychology, and especially the stress Bentham put on the role played in human behavior by calculation of gain or loss. He objected also that Bentham, by shifting from a technical (or broad) meaning of terms—and especially of the term "interest"—to a popular (or narrow) meaning, often slid into an account of human behavior which pictured it as inherently selfish. He explained this—unkindly—in terms of Bentham's personality. Bentham, said Mill, intellectually recognized the possibility of generous action, of benevolence, but "the incompleteness of his own mind as a representative of universal human nature" led him to regard genuine benevolence as rare and therefore unimportant in real life.

In many of the most natural and strongest feelings of human nature he had no sympathy; from many of its graver experiences he was altogether cut off; and the faculty by which one mind understands a mind different from itself, and throws itself into the feelings of that other mind, was denied him by his deficiency of Imagination.²⁰

There was a basis for Mill's criticisms. That Bentham frequently fell into language which pictured human behavior as if it consisted almost solely of action based on calculations of personal gain and that his imagination was deficient with respect to the possible range of human emotions is beyond dispute. But Mill goes further in his criticism at some points than the texts he cites, or their context, justifies, and in doing so disregards peculiarities of the Benthamite terminology which at other times, when his attitude had changed, he was to invoke against misinterpretations of Bentham at other hands. I can here deal with only one of these misinterpretations. Mill points out that if in

²⁰ "Bentham," reprinted in J. S. Mill, *Dissertations and Discussions*, 3rd ed., L. 1875, I. 353.

Bentham's *Table of the Springs of Action* we find such words as "Conscience," "Principle," "Moral Rectitude," "Moral Duty," which in the mouths of others represent recognition of such a thing as conscience as a thing distinct from philanthropy, affection, or self-interest in this world or the next, it is as synonymous for "love of reputation," and that the word "self-respect" appears not at all either here or in any of Bentham's writings.²¹ The critics of Bentham who have since made the same criticism and cited his *Table of the Springs of Action* as evidence are beyond enumeration.

There is only too much ground for criticism of Bentham for not using words quite as other men do, provided that deviation on his part from the common use of terms is not taken as reliable evidence of deviation from the common run of thought on the questions with which these words are usually associated. But Mill, who should have known better, makes use here of this kind of argument against the one person of all who by his discussions of the logic of language had made himself least vulnerable to it. Moreover, Bentham in his writings does use "conscience" and "duty" very much as other men do, and if he did not use "self-respect," his stock of synonyms was adequate to fill the void.

The *Table of the Springs of Action*, however, itself provides a more direct, though only a partial, answer to Mill's criticism. The psychology of Hartley and of James Mill from which Bentham started distinguished between "simple" pleasures, and "complex" or "compound" pleasures derived from the "simple" ones genetically by the processes of "association of ideas." Benevolence, generosity, duty, justice, conscience, and so forth would be "compound" pleasures. But Bentham expressly says of the *Table*—which is sufficiently formidable as it stands—that: "The pleasures and pains here brought to view are, every one of them, *simple* and *elementary*."²² He does cite a few "Compound Pleasures," as illustrative of one broad category of such excluded from the table. One of these, "Love of Justice," has as one of its components "Sympathy for the community at large, in respect of the interest which it has in the maintenance of justice." Mill was later to emphasize love of justice as one of the major virtues. His present refusal to be satisfied with Bentham's recognition of it as one of the "Springs of Action" was perhaps a not too captious suspicion that the words added to it by Bentham made of it a less admirable virtue than if Bentham had written merely "Love of Justice (Period)." But it was common ground among the Benthamites, including J. S. Mill, that the tone and moral significance of "compound pleasures" could be radically different from

²¹ *Ibid.*, I. 359.

²² *Works*, I. 207.

the tone and original significance of their component elements, the "simple pleasures" from which they had been compounded. ✓

By the time Mill was working on his *Principles of Political Economy*, he had swung back a large part though not all of the way to Bentham's political theory and moral philosophy. What was left of his revolt was confined mostly to a continued insistence on recognition of the complete range of human feelings and a consequent endeavor to avoid exaggerating the role of rationalistic hedonism in human behavior.

William Whewell, an anti-utilitarian professor of moral philosophy at Cambridge University where an even narrower type of utilitarianism with hell-fire trimmings—"theological utilitarianism," it was later to be labelled—had until his advent reigned unchallenged for over a century, in 1838, on the appearance of Mill's article on Bentham, had in private correspondence with a friend welcomed Mill's recantation, but complained—with some justice—of its manner:

It is certainly very encouraging to see on all sides strong tendencies to a reform of the prevalent system of morals. The article [by Mill] in the *London Review* is an indication of this, and appears to me to be in many important points right, and at any rate right in the vigorous rejection of Bentham's doctrines and keen criticism of his character. But I confess I do not look with much respect upon a body of writers, who, after habitually showering the most bitter abuse on those who oppose Bentham's principles, come round to the side of their opponents, without a single word of apology, and with an air of imperturbable complacency, as if they had been right before and after the change. Nor do I see any security, in their present creed, against a change of equal magnitude hereafter.²³

This was real prescience on Whewell's part. In 1843, in conversation about the surviving disciples of Bentham, Mill made the remark which "though smilingly uttered . . . was not at all a jest" that as for himself: "And I am Peter, who denied his Master."²⁴ In 1852 Mill was to write a critical review of Whewell's *Lectures on the History of Moral Philosophy in England*, published in the same year. Conceding very little error in the Benthamite doctrine, Mill rejected vehemently Whewell's objections to utilitarian ethics in general and to Bentham in particular, even when they were very similar indeed to his own criticism of Bentham in 1838.

The final stage in Mill's presentation of his ethical views was in 1863, when his essays on Utilitarianism appeared. In form, these still represented an adherence to the doctrine, but so modified by the admission without obvious absorption of foreign elements that they have

²³ Mrs. Stair Douglas, *Life of William Whewell* (London, 1881), pp. 270-71.

²⁴ David Masson, "Memories of London in the 'Forties,'" Blackwood's, Vol. CLXXXIII (1908), p. 553.

been the despair of its friends and the delight of its critics ever since. Acts were to be morally appraised solely in terms of their consequences for happiness—a strictly Benthamite proposition. *All* consequences, however, were to be taken into account, including the effects on the character of the agent—an early doctrine of Mill's, which he derived from Coleridge and which he regarded as contrary to Bentham's views, mistakenly, I think. Happiness was conceived broadly enough to cover every type of wish or aspiration man could experience. Mill—unwisely, I think—went a step further than Bentham ever ventured by offering a “proof” that happiness was the proper criterion of virtue: namely, that competent judges accepted it as such, a type of proof which eighteenth century critics of the “moral sense” school of ethics had exposed to ridicule for its circularity.

Mill now attempted also to incorporate into utilitarianism a novel element for it and one which many moral philosophers hold to be incompatible with it, namely, the recognition of non-homogeneity of pleasures and consequently the existence of qualitative differences of a hierarchial nature, as well as quantitative differences, between pleasures:

It is quite compatible with the principle of utility to recognize the fact, that some *kinds* of pleasure are more desirable and more valuable than others. It would be absurd that while, in estimating all other things, quality is considered as well as quantity, the estimation of pleasures should be supposed to depend on quantity alone.²⁵

The test of quality as between two pleasures was the preference “by those who are competently acquainted with both” of the one above the other despite the fact that the other represented a much greater quantity of pleasure.²⁶

I venture to suggest: (1) that the problem as Mill presents it, that is, within the limits of utilitarianism, is a spurious one; (2) that what he proffers as a solution is even more spurious; and (3) that Bentham and his predecessors to some extent and modern economists using utility theory to a larger extent, have provided a technique which, while it does not solve any fundamental moral problem, suffices to show that a dichotomy and possible clash between ratings of values on the basis of quality and their rating on the basis of quantity is not one of the fundamental moral problems.

²⁵ J. S. Mill, *Utilitarianism*, 3rd ed. (London, 1867), pp. 11-12.

²⁶ *Ibid.*, p. 12. In an undated manuscript “On Social Freedom,” found in Mill's house at Avignon after his death, and published, among other places, in *Living Age*, 7th ser., Vol. XXXVI (1907), pp. 323-36, there is a stronger statement of the higher-lower thesis with the order of rank made a pure matter of “feeling,” not subject to demonstration or to argument—a complete swing back to the eighteenth century “moral sense” school.

Pleasures—or desires—are of course not homogeneous with respect to every conceivable quality they may possess—any more than are any other objects of human attention except abstract numbers. Comparison is—or should be—always with respect to specified qualities of objects, and if there is possibility of and proper occasion for measurement the measurement is also with reference to these specified qualities.

Mill confuses the issue by attempting at the same time to give predominant importance to the ordering of *classes* of pleasures on a higher-lower scale and to leave room for legitimate preference in particular cases of a pleasure of a lower order over one of a higher. This is the famous and ancient false dilemma of the water-*versus*-diamonds problem in economics, extended to the whole field of values. Whatever may be the case for didactic purposes, for actual behavior—including “moral” behavior—the issues arise in the form of necessary choices between units and not between classes of objects. Bentham’s famous dictum “Quantum of pleasure being equal, pushpin [a children’s game] is as good as poetry” would meet all the proper requirements of the utilitarian principle if restated somewhat as follows: “Desire being equal at the margin of choice, a marginal unit of pushpin is as good as a marginal unit of poetry.” The utilitarian but didactic moralist would still be free to insist that since in fact experienced choosers don’t plump for even a first unit of pushpin until they are gorged with poetry, *in that sense* poetry as a class is higher on the scale of values than pushpin as a class.

I come now at long last to Mill’s *Principles of Political Economy*. He wrote this two-volume book in less than two years, and when he began it he expected it to take only a few months to write. For at least ten years prior to this, he had not given much attention to economics. It was designed to do for Mill’s time what Adam Smith had done for his, and to present what was known of the “Principles of Political Economy” as a science, together with their applications to concrete problems and, in the words of its title page, “some of their Applications to Social Philosophy.” By the “science” of political economy Mill meant a body of deductive analysis, resting on psychological premises derived from introspection and observation of one’s neighbors, and even with respect to these premises abstracting from all aspects of human behavior except those most intimately and most generally associated with the business of buying and selling. When Malthus, in 1824, objected that the “new school” of Ricardians had “altered the theories of Adam Smith upon pure speculation,” Mill had replied: “it would, indeed, have been somewhat surprising if they had

altered them on any other ground."²⁷ Later, as the result of Comtean influence and of his investigations in logical method, Mill was more receptive in principle to the possibilities of historical induction. But it is clear that he never assigned to it the right to an independent role in the "science" of political economy. Writing in 1835 with respect to the historical form of the inductive method, he had said:

History is not the foundation, but the verification, of the social science; it corroborates, and often suggests, political truths, but cannot prove them. The proof of them is drawn from the laws of human nature; ascertained through the study of ourselves by reflection, and of mankind by actual intercourse with them. . . . The usefulness of history depends upon its being kept in the second place.²⁸

This was, of course, standard methodological doctrine, and to a large extent practice, in English social thought since Hobbes. Inquiry was to be pursued by means of deductive reasoning resting on psychological premises obtained empirically, but chiefly through introspection—which, it should always be remembered, was universally regarded in the past, whatever may be the fashion today, as an "empirical" technique of investigation, and sharply distinguished from intuition, or "innate ideas." But in J. S. Mill, as methodological doctrine, it has less significance than for most of his predecessors, since he confines it to the "scientific" part of Political Economy, stresses the importance of "applications" which can proceed by a wider range of logical methods, gives repeatedly at least platonic warnings that any abstraction from reality must be allowed for before the results of such analysis are made the basis for pronouncements on policy, and rejects it for every other established branch of social thought.

Of his earlier rebellion against the psychology of Bentham and of his father, the most important residue for his economics was probably his repeated emphasis on the importance of custom as a rival to the competitive principle, especially in connection with land-tenure and the relations of landlord and tenant. Here he showed the influence of Richard Jones, one of the pioneer advocates of resort to systematic induction in economics. But this presented J. S. Mill with somewhat of a methodological dilemma, which he never succeeded in resolving. "It is unphilosophical," he wrote, "to construct a science out of a few of the agencies by which the phenomena are determined, and leave the rest to the routine of practice or the sagacity of conjecture."²⁹ On

²⁷ In a review of the article by Malthus in the *Quarterly Review*, No. LX, criticizing McCulloch's "Political Economy" article in the *Supplement* to the fourth edition of the *Encyclopaedia Britannica*, *Westminster Review*, Vol. III (1825), p. 213.

²⁸ "Professor Sedgwick's Discourse on the Studies of the University of Cambridge," *Dissertations and Discussions*, Vol. I, pp. 112-13.

²⁹ *A System of Logic*, 3rd ed., Vol. II, p. 472.

the other hand, "only through the principle of competition has political economy any pretension to the character of a science,"³⁰ a proposition which F. Y. Edgeworth was later in effect to repeat, when he wrote that if monopoly should prevail over a large part of the economic order:

Among those who would suffer by the new regime there would be [included] . . . the abstract economists, who would be deprived of their occupation, the investigation of the conditions which determine value. There would survive only the empirical school, flourishing in a chaos congenial to their mentality.³¹

We seem, however, to have found another alternative, that of becoming amateur lawyers.

Mill thus had no technique for dealing systematically with the analysis of economic process where competition was encroached upon either by custom or by monopoly, and when he did mention custom—or monopoly—he left it to the reader to estimate its importance and to make the necessary corrections in the conclusions he had reached on the basis of abstractions from these complicating factors. For himself, he assumed the responsibility only for that "uncertain and slippery intermediate region," between "ultimate aims" and "the immediately useful and practicable."³² Logicians and physical scientists have the right, I suppose, to jeer at Mill's failure to extricate himself from this plight. For those among us, however, upon whom the redeeming grace has not as yet been bestowed of that special ideology which takes the form of faith in the capacity of statistical method to perform logical miracles, humility is prescribed, since we are all in the same fix.

The *Principles* thus has no single methodological character. As is the case with the *Wealth of Nations* of Adam Smith, some portions are predominantly abstract and *a priori*; in others, there is a substantial measure of factual data and of inference from history. Its wide range of subject matter; the success with which the lucidity of its style and the nobility of its outlook on life divert attention from its lack of logical rigor; the patent honesty and open mindedness with which controversial issues are treated; these and other qualities made it probably the longest-lived textbook our discipline has ever had or ever will have. It was the text used in the first college course in economics I took, over sixty years after its first publication. Francis Walker's *Political Economy* was also assigned to us, and I think we showed good judgment when we labelled the course, as students will, "Milk and Water." Writing in 1832, Mill had presented a forceful case in defense

³⁰ *Principles of Political Economy*, Bk. II, Chap. IV, "Of Competition and Custom."

of ambiguity in language, on the ground that it was for many persons the price which would have to be paid if important ideas which by their richness and variety of content it is difficult to make clear were not to be sacrificed on the altar of logical clarity.³³ The *Principles*, I think, demonstrate that for Mill himself this was good doctrine; it would have been an inferior book, much less rich in content—and much smaller in size—if Mill had thrown out all that was ambiguous and lacking in strict logical consistency. ✓

What most struck his contemporaries in the contents of the *Principles* was the sympathetic manner in which Mill dealt with proposals for radical change along socialist lines in the economic structure of society. The sympathy was in large degree platonic, for in no major concrete instance did Mill actually commit himself to the desirability of a specific drastic change. Mill aspired after the millennium, but he found abundant reason why it was not and should not be wished to be imminent. He looked forward, mostly on ethical and humanitarian grounds, to substantial socialization of the institution of property at some time in the vague future. Meanwhile, however, he warned against any weakening of the institutions of private property, free competition, and the rule of the market. This combination of hard-headed rules and utopian aspirations was just exactly the doctrine that Victorians of goodwill yearned for, and it made a large contribution to the popular success of the book.

Mill's handling of the problem of laissez-faire was a case in point. Except for the difference in tone and feeling, the fuller expression of lofty ideals and impracticable aspirations, it was substantially similar in method of analysis and nature of conclusions to Bentham's treatment. Like Bentham, and like all the other major classical economists except perhaps Senior—who was not a Benthamite—J. S. Mill gave only a very qualified adherence to laissez-faire. It was for him only a rule of expediency, always subordinate to the principle of utility, and never a dogma. The dogmatic exponents of laissez-faire of the time were the Manchester School, and Mill—like Torrens before him and Cairnes, Jevons, Sidgwick, Marshall, Edgeworth and others after him—denied repeatedly, and forcefully almost to the point of blasphemy, that the Cobdenites had either authority or logic to support them when they invoked the "Laws of Political Economy" to stop government from coming to the relief of distress.

It is, fortunately, not part of my assignment to appraise the technical economics of Mill's *Principles*. What I have tried to do is to show the intellectual relations between two men important in the history of our

³³ Review of G. C. Lewis, *Use and Abuse of Political Terms*, *Tait's Edinburgh Magazine*, Vol. I (1832), p. 164 ff.

discipline. From these two men several generations of British and American—and above all Canadian—economists, and to some extent also “liberal” continental economists, derived in large part the psychological, ethical, political, and methodological presuppositions upon which they built their economic analysis. With the ebbing of liberalism in the profession, the importance of knowing what its intellectual foundations were has become chiefly historical, and to those under fifty the historical is not obviously important. But for those *over* fifty, a comment of Tawney’s is relevant. “It is a wise philosopher,” he writes, the flatterer really meaning “economist,” “who knows the source of his own premises.”³⁴ I would go even further. It is an unusually alert economist who knows what his premises are, regardless of their source. For those over fifty study of Bentham and of Mill can do something to remedy both of these lacks. Beyond this remark, I make no attempt to draw any moral from what I have said. But I believe that in exercising this unaccustomed measure of self-restraint I am conforming to the “Principle of Utility” if broadly enough interpreted.

³⁴ Introduction to Raymond W. Firth, *Primitive Economics of the New Zealand Maori* (London, 1939).

PUBLIC EXPENDITURE POLICY

By PAUL J. STRAYER*

An increasing number of economists and political scientists are becoming concerned about the role of government in the economic affairs of the nation. Much of the recent writing on the subject has been negative and has emphasized the dangers of increasing governmental controls without offering any satisfactory solution to the problems that have made the increase inevitable.¹ On the other hand, most advocates of positive government intervention have not established a satisfactory basis for the long-run adjustment of relationships between the private and public sectors of the economy. This deficiency is recognized by such writers as J. M. Clark, F. D. Graham and Henry Simons.² Their greatest contribution has been their emphasis on positive long-run suggestions. This is a healthy trend and has been of great value. However, much more investigation and groping for solutions will have to be undertaken if guidance and leadership is to be given by moderate economists who would like to see the social and economic issues of the day met without resort to a planned economy. In particular, more attention must be directed to the problem of administration and the political implications of positive government economic programs. The inevitable interrelation and interaction of administrative and political forces with purely economic forces must be given greater emphasis if policy formulation is to be realistic and effective.

I. *Expansion of Government Influence*

One of the major difficulties of the present situation is the rapidity with which the expansion of direct government influence in the determination of market conditions has taken place. Prior to World War I, government finance was a minor factor. Even after World War I, the return to normalcy left the government in a relative insignificant position. It was not until the depression of the 1930's continued to the point where the inability of private business or private charity to cope with the situation was generally recognized that government became a major

*The author is assistant professor of economics in the department of economics and social institutions at Princeton University.

¹ For example, see L. von Mises, *Omnipotent Government* (New Haven, 1944) and F. A. Hayek, *The Road to Serfdom* (Chicago, 1944).

² J. M. Clark, *Alternative to Serfdom* (New York, 1948). F. D. Graham, *Social Goals and Economic Institutions* (Princeton, 1942). H. C. Simons, *Economic Policy for a Free Society* (Chicago, 1948).

factor in the determination of the economic welfare of not only the recipients of relief and assistance but also of the entire private sector of the economy. The rise of the New Deal was the outgrowth of the impact of these events. However, the tentative nature of early New Deal spending and the annual promise that the budget would be balanced the *next* year, indicated that there had not yet developed a consistent theory or program that would permanently give to government a major role in the economic life of the nation.

It was not until the publication of *The General Theory of Employment, Interest and Money* by John Maynard Keynes that the beginnings of a consistent theory for short-range government intervention was formulated. It was no accident that the rise of the inner circle of "New Dealers" who advocated the conscious use of fiscal policy, without regard to established tradition, dates from the publication of this book in 1936. The development of the concept and measurement of the national income also aided in the formulation of a short-run theory and has given statistical support to the belief that variation of the government net cash surplus or deficit could offset fluctuations in effective demand in the private economy. The appeal of the fiscal approach was that it did not depend upon an understanding of all the basic reasons for fluctuations in the private economy but could be turned on or off as necessary.

The limitations of the Keynesian and neo-Keynesian theory have become more obvious in the period since the end of World War II. Fiscal policy was designed to use in periods of depression. Its logic can also be applied to control inflationary developments but the practical difficulties are much greater than in depression. The fear of many economists today is that reliance on fiscal policy to support full employment may be impossible as an inflationary bias arising out of monopolistic trade union activity and large industrial concentrations may permit both unemployment and inflation to occur simultaneously.³ There is also need for much more discussion than has yet taken place of the basis for the selection of the controls necessary to achieve the income effects desired to stabilize the economy.

In spite of the limitations of recommendations made to date, there is little reason to believe that we can return to the general acceptance of the role of government that prevailed in the pre-depression era. The passage of the Employment Act of 1946 and the commitments of both political parties to support a stable economy are testimony to the fact

³ A. G. Hart, "The Problem of Full Employment," *Proceedings, American Economic Review*, Vol. XXXVI, No. 2 (May, 1946). J. J. Spengler, "The Role of the State in Shaping Things Economic," *The Tasks of Economic History*, Suppl. No. VII to *Journal of Economic History*, 1947.

that the government is bound to play a more important rôle than ever before. The magnitude of the level of government outlays has increased both absolutely and as a percentage of the total national income. Our times are not likely to see the trend reversed. The level of taxation has increased proportionately and the severity of current levies is such that the impact of federal taxation alone may be greater than any other force that can be isolated for separate consideration by the average citizen or business concern.⁴ Management of the public debt now dominates the securities markets and government debt policy is more significant than the combined decisions of the largest financial houses in New York. Banks and the banking system are directly affected by the debt policy of the government and the whole theory of central banking policy has been permanently affected by the growth and influence of Treasury operations.⁵

It is significant that this growth in government influence has not been the result of a program of increased government ownership of the productive resources of the nation but is largely the result of the tremendous increase in the extent of transfer expenditures, the increase in war and defense outlays (production of war equipment still in the hands of private producers), and the rapid expansion in the level of foreign commitments and requirements in the postwar world.⁶ The increase in direct control of factors of production that has taken place in the TVA and in the steady increase in public services such as public education, health, and housing have been less important in their effect on the aggregate. With the exception of the expansion in the field of river basin development along the lines of the TVA, and the possible expansion in the role of government in the field of atomic energy, there is no immediate indication that further expansion of government ownership of production will take place.

II. *Administrative and Political Problems*

At the same time these revolutionary changes in the role of government in the economy have been evolving, equally important changes

⁴L. H. Kimmel, *Governmental Costs and Tax Levels* (Washington, 1948). Kimmel estimates tax collections by the federal government will have increased from 6.3 to 14.5 per cent of the national income between 1940 and 1952 and for all governmental levels from 18.8 to 24.8 per cent in the same period (p. 131). This is a very conservative estimate.

⁵Two articles by H. C. Simons and the recent study by C. C. Abbott are good offsets to the assumption of the more extreme Keynesians that the public debt can increase indefinitely. See H. C. Simons, *op. cit.*, Chapters IX and X, and C. C. Abbott, *Management of the Federal Debt* (New York, 1946), *passim*.

⁶Kimmel's estimates for 1952 indicate a probable cash expenditure of 40.5 billions by federal, state and local governments. Of this total, national defense, veterans' benefits, interest on public debt and foreign loans and relief account for 20.6 billions. L. H. Kimmel, *Governmental Costs and Tax Levels* (Washington, 1948), p. 12.

have been forced by the course of events in the field of political organization and control, and in the field of public administration. As is the case in the evolution of the changing conception of the economic role of government, the political and administrative changes have been tentative and have yet to jell into a clearly defined pattern. As yet no theoretical framework has been developed that would compare in influence to the work of Keynes and the issues have been less clearly defined than in the case of the debate over the economic role of government. The magnitude of the change is no less, however, and the need for reappraisal of political and administrative processes of government no less important. The most severe barrier to the modification of political and administrative practice to meet new conditions is found in the rigidity of the basic structure of American government with its emphasis on the division of power between the three branches of government and the unfortunate pattern of the boundaries of the state and local governments. The result has been that major innovations have been accomplished by the creation of new methods of control superimposed upon the old antiquated structure or by the temporary ascendancy of the executive. As the economic changes have brought reaction, so the political and administrative improvisation to meet new conditions have been fought by groups who oppose any change in the patterns established over the years.

The importance of the political and administrative aspects of the new role of government is no less than the purely economic. Whether success or failure is to be achieved will be determined as much by the way in which the controls are administered and decisions made as by our understanding of the basic economic conditions and influences.

These introductory paragraphs suggest that the formulation of policy or recommendation of a positive program is much more difficult than has been admitted by most writers in the field of fiscal policy. They have tended to look at the arithmetic of the situation as revealed by models constructed on the basis of national income estimates and have neglected the extent and severity of the repercussions of the actual measures that would be necessary to implement their programs of government stabilization of effective demand. A new approach to the role of government has to be developed to replace older concepts or to serve as a complement to them. A brief review of some current expenditure policy suggestions will reveal how much is yet to be done before a coherent and effective framework may be constructed.

III. *Theory of Public Expenditures*

Prior to the Great Depression of 1929 most discussions of government expenditure policy assumed full employment. The role of the

state was restricted to preservation of law and order, national defense, provision of certain social services, expenditure for the preservation and development of the natural resources, and limited investment in generally approved public works. The typical discussion developed the dogma that the least government was the best and that the burden of proof for increasing government expenditures should rest on the advocates of expansion. No rules that would permit the translation of these generalizations into definite figures were devised. It was assumed that expenditures would not change radically in the short run although much comment was devoted to the long-run trend toward higher outlays.

The inadequacy of these generalizations was well understood by John Stuart Mill when he wrote, "But enough has been said to show that the admitted functions of government embrace a much wider field than can easily be included within the ring-fence of any restrictive definition, and that it is hardly possible to find any ground of justification common to them all, except the comprehensive one of general expediency; nor to limit the interference of government by any universal rule, save the simple and vague one that it should never be admitted but when the case of expediency is strong."⁷

The long-run tendency for rising expenditures on the part of all levels of government in the United States has continued in spite of frequent assertions of the traditional doctrine, the desirability of minimal public activity. It is this shift to increased government and less private control that is the basis of most of the objections to further expansion of government. However, in spite of all protests, demands for increased appropriations tend to be more frequent and potent than demands for reduction. The failure of periodic Congressional drives for budget curtailment is evidence of the power of public demand for high-level appropriations.

A satisfactory theoretical solution of the problem of distribution of government and private expenditures has not yet been advanced. The suggestion made by Hart that "the common sense of public expenditures is to carry them to the margin at which they are of equal social value with alternative, private expenditures of equal amount, irrespective of revenues,"⁸ is too narrow to be of much use in the formulation of policy. It ignores the fundamental source of difference among those interested in the effects of alternate policies on the basic economic and political institutions of the country. It is also impossible to arrive at a reasonable judgment on the merits of a particular level of expenditure

⁷ John Stuart Mill, *Principles of Political Economy*, Book V, Chap. 1.

⁸ A. G. Hart, "National Budgets and National Policy: A Rejoinder," *Am. Econ. Rev.*, Vol. XXXVI, No. 4, Pt. 1 (Sept., 1946), pp. 632-36.

without consideration of the repercussions of alternate means of raising the necessary revenue. This is just as important when new money or credit is used as when the revenue is obtained by taxation. The generally accepted imperfections of revenue, monetary and credit systems in the United States gives additional force to this argument. Even if there were a perfect tax system and the control of money and credit left nothing to be desired, the difference between public and private financing of a given level of expenditures would be significant and have to be weighed in the decision as to the proper balance. No marginal analysis can give even an approximate answer to such questions as these. Finally, there are differences in the effects and implications of different levels of government expenditure at different levels of employment and national income. It has been suggested that the level of public expenditures, except transfer expenditures for relief and other forms of assistance, should be appropriate to an estimated "normal" national income and fluctuations in income ignored.⁹ The bias of the writer is in this direction but the reasons for such a policy are much more political than economic. A decision to follow such a course must neglect or weigh lightly the changes in relative availability of factors of production and changes in the needs and demands of the community over the cycle or in contrasting periods of secular stagnation or boom.

Still more difficult is the treatment of the exogenous forces that loom so large in the budgets of today, such as war or the repercussions of war, political and moral commitments to other nations, and the operations of pressure groups and vested interests which have proved to be successful in obtaining subsidies or special privilege at the expense of the rest of the country. The fact is, that in the United States today there is a very limited area where the voter has an opportunity to weigh or consider the advantages and disadvantages of alternate expenditure policies.

One must conclude that the hope of obtaining unbiased advice and guidance from the economist or student of public finance on the question of public expenditure is dim. The subjective judgments of the writer are of much greater significance in determination of his position than are the tools of economic analysis. He can be of service, however, in presenting fully his estimate of the possible implications of alternate policies for the education of the public. Policy decisions should be made on the basis of the fullest possible information. There is still much that needs to be done to raise the level of the debate to the point where decisions will be based upon true wishes of the majority. There will always be differences of opinion. It is to be hoped, however, that

⁹ See Milton Friedman, "A Monetary and Fiscal Framework for Economic Stability," *Am. Econ. Rev.*, Vol. XXXVIII, No. 3 (June, 1948), pp. 245-64.

they will be brought to the surface and more fully explored in the future than they have been in the past.

IV. *Expenditure Trends*

The trend for larger and larger social service outlays has been established for many years. Needs for government services have grown with the technological developments and with the rise of urban concentrations of population. However, the most spectacular increase in government expenditure has been in the field of national defense and war. This reflects both technological developments and a changing conception of warfare in the modern world. Total war is a new development and the experience of World War II indicates that it requires the complete mobilization of all economic and social resources if it is to be prosecuted effectively. The next most important cause of growth in expenditures is the increase in transfer expenditures: for debt service, for social welfare and security, and for the veteran. It is obvious that a large part of this increase can be attributed to the past war.

The significance of this trend is much greater than the immediate impact of the benefits or costs to the various segments of society. In the process of granting benefits and imposing taxes necessary to finance this new level of outlay, political and administrative decisions are becoming more and more significant in economic affairs. The character of output, the distribution of the output, and the total amount of production are all affected in ways that do not conform to the ideal of a free-market system. The only reason government and political influence have not been even more pervasive is that, at the same time the absolute and *per capita* level of government expenditures have been increasing, total national production has also been increasing. If the total national product should decline, there is no question that the percentage of the total controlled by government would increase at a more rapid rate. If this trend continues, the growth of government influence will give to government such a preponderance of authority that the chief characteristics of the free-market system will disappear.

The strength of the forces leading to further expansion of government expenditures is revealed if one surveys the recommendations of various professional groups concerned with the adequacy of the level of services and functions already performed by government. Convincing cases can be made for increased direct and transfer expenditures for public education, housing, health, old age assistance, defense, transportation, recreation and so on.¹⁰ Unless the productivity of the private

¹⁰ See estimates in J. Frederic Dewhurst and Associates, *America's Needs and Resources* (New York, 1947), *passim*.

economy increases over the years, the trend toward higher public expenditures will result in the government domination that was suggested above.

It is this point that has made the case for government compensatory spending so persuasive. The one thing that the private economy cannot tolerate is continued depression or stagnation. The productivity of the private economy must increase steadily if it is to survive. The danger is real as an even more rapid growth in public expenditures than yet experienced may be in prospect. This is certain if either widespread dissatisfaction with the private economy develops or large-scale defense appropriations continue to be necessary.

A second major argument for the use of government expenditure variation as a means of stabilizing the economy is that when there are unemployed resources the cost to society of the employment of idle factors by government is zero. Support of the private economy achieved in this fashion will temporarily shift the balance in favor of greater government control of production but this should be a temporary phenomenon if the activity is restricted to the period of depression.

V. Limitations of Expenditure Manipulation

The major issue is whether the government can vary its level of expenditures over the cycle without permanently increasing the proportion of the economic life of the nation under government control. It is this that private business fears, and not without reason. For example, counter-cyclical planning of public works has been suggested as the most effective means of supporting effective demand in a depression and at the same time making direct provision for unemployed workers. If it were possible for public works to be transferred from periods of prosperity to depression, the long-run level of public activity could be maintained constant. It is more likely, however, that the public will not permit the variation of public works expenditures in this fashion.¹¹ It is reasonable to suggest that, except for effects on employment and income, public works outlay should be greatest in

¹¹ Gerhard Colm's discussion of recent experience is revealing. He writes as follows: "The limits of an effective fiscal policy through manipulation of expenditures were demonstrated in August, 1946, when President Truman wanted to curtail expenditures as one of the measures for combatting inflationary pressure. He cut by two billion dollars a Federal budget that exceeded forty billion dollars. The rest of the budget was regarded as largely inflexible because it is determined by legislation or allocated for Government purposes that were believed to be nondeferrable. It proved difficult to enforce even this limited curtailment program in view of resistance against the postponement of certain public works. The experience showed not only that flexibility in the Federal budget is limited, but also that our legislative and administrative machinery is not yet fully equipped to use even this limited existing flexibility." Gerhard Colm, "Fiscal Policy" in *The New Economics*, Seymour E. Harris, editor (New York, 1948), p. 464.

periods of prosperity and least in periods of depression. This follows from the fact that expansion in real income and activity leads to more extensive use of public facilities and demand for entirely new facilities. Auto and truck mileage increases, recreation facilities are more frequently used, school enrollments increase and schooling is continued for a longer time, water and power consumption increases and postal demands grow in periods of prosperity. These needs can be met only if public investment is increased. It does not make sense to tell voters that they should postpone their demands for better facilities until the uncertain day when there will be a depression. If existing facilities are inadequate, and they usually are, it is difficult to criticize the voter who demands immediate correction of this deficiency.

The selection of the most appropriate types of public works also raises many issues not yet solved. As the amounts involved in any works program must be large if real benefits are to be achieved, the choice of the most appropriate works is a major consideration. Unfortunately, consideration of projects on the basis of the need for improvements may lead to conflict with the private economy. If public works conflict with private industry, the discouragement to private investment that will result may perpetuate the very evil that the government is trying to correct. Another dilemma is that the reversibility of public investments tends to be in inverse relationship to the need for the project. Thus, the most useful of all programs that might be suggested at the present time is the development of other river basins along the lines of the TVA. Another project with a high priority would be the expansion of public housing. In either case, the project or projects, once under way, would be difficult to stop and might well be continued until they competed directly with the private economy for materials and labor and were the cause of inflationary price movements. The extent of this danger can be minimized by careful control and planning but it is likely that the results would be adverse to the private economy.

It has been suggested that these objections could be met if a public works program were planned on the basis of *future* needs. Thus, roads could be built to take care of future traffic, schools could be built and partially utilized in anticipation of future growth, and so forth. When prosperity returned, the problems of slowing down the rate of expenditure or stopping some projects entirely would not be difficult, so it is argued.

A critical examination of this suggestion reveals that it sounds more plausible than it is. In the first place, emphasis on future needs would tend to direct resources and labor to the less important jobs left to be done. As long as there are deficiencies in essential government service

and the need for the development and protection of natural resources continues to be as great as it is today, there is no practical limit to the amounts that could profitably be spent on improvement in these areas. Under these circumstances, how can the construction of a highway that is not needed at the moment be justified when there are thousands of miles of dirt roads left in the country? How can schools larger than needed in the immediate future be constructed when there are thousands that are below standard that should be replaced? Can a new post office be justified if the local hospital is inadequate to care for all the sick? Can housing that would be used immediately be neglected to build a community center adequate for the next fifty years?

As long as the current level of public service falls as short as it does of the public needs there is little chance that this approach will prove acceptable. Additional complications arise if the inadequacy of economic forecasting is considered. Predictions would have to be made that would determine the pattern of expansion of the country for years to come. If these proved to be as inaccurate as is usually the case, the waste and distortion of the economy would be so great that it might discredit the entire program. This sort of guessing game would also be an invitation to the pressure groups and lobbyists to come and feed at the public trough.

Suggestions to vary public works outlays have not been restricted to the benefits to be derived from the aggregate effects of such programs. It is argued that selective works programs are effective and desirable as a means of aiding specific industries or areas that are depressed and require special attention.¹² Thus, the construction industry has proved to be more vulnerable than the average industry and should receive special support. Similar cases can be made for most heavy investment industries and areas where these industries are major employers. Although not aided by a public works program, agriculture is another case where special action has been recommended and put into effect as a part of a campaign to relieve areas of greatest need.

There is no question that a realistic view of the needs and political demands of the public requires that provision be made for special cases beyond the general provisions of a recovery program. This does not justify the claim, however, that recovery may best be promoted by selective expenditure programs. Programs of this type may establish dangerous precedents and invite irresponsible political action designed to gain temporary political advantage for narrow pressure groups. Rather than correcting basic maladjustments, a selective program may prolong adjustment to changing conditions, or to changing technology

¹² A. H. Hansen, *Fiscal Policy and Business Cycles* (New York, 1941), pp. 262-63.

required to give maximum efficiency in the satisfaction of wants and utilization of resources. There is also danger that support will be given to monopolies or semi-monopolistic industries at the very time they are losing their monopoly power. A strong case may be made for selective programs attempting to maintain a balance between investment and consumption. Anything more requires greater precision than has yet been gained in the definition of the criteria for eligibility. What is a distressed industry or area? If an area or industry is to be given special relief, by what process is the relief to be tapered off? What rate of return should be allowed a subsidized industry? These are but a few of the questions that arise if selective control is considered.

The greatest danger of selective relief programs is that they will weaken the effectiveness of the free-market system by preventing losses from exercising their logical influence on the transfer of resources, labor, and management from declining to expanding industries. On the other hand, there is no possibility that the free market can be left to operate without some tempering of the severity of its influences in special cases. The problem can be solved if provisions for easing the impact of temporary unemployment in individual cases are improved. This involves expansion and liberalization of the provisions of unemployment insurance and dismissal pay, and the creation of an effective system of national employment offices. In the event of a major depression it is suggested that primary reliance be placed upon less selective means of promoting recovery until job opportunities are once more available to displaced workers.

Finally, counter-cyclical variation in government works expenditures runs up against a whole host of difficulties of a purely political and administrative nature. Most of these are familiar to even the most superficial student, but the one that deserves the greatest attention is often neglected. This is the possible effect of works programs designed to stabilize the economy on the structure of local government. One of the prized features of the political system of the United States is the reliance on local initiative and responsibility to provide the primary wants of the people in the community. Until relatively recent years this was possible and done rather well. Since the 'twenties it has become increasingly apparent that the old local government units can not do the job. Financial strength and administrative power are lacking. The first result has been to greatly increase the role of state governments and the extent of federal aid. On the whole, this has been to the advantage of all groups but the loss of local responsibility and initiative is a high price to pay. There is also danger that the centralization of power in the federal government will result in a form of corruption that will make the exploits of the city machines seem mild in comparison. This

was the fear of Henry Simons who believed that the activities of pressure groups and lobbyists had already brought this result in the period of the New Deal.¹³ What is feared is that decisions made by the central government will not represent the true needs of the people, but will lead to the diversion of billions of dollars into worthless projects that are of little good to anyone but have the backing of the most powerful lobbies in the national capital. This problem would be aggravated by the increased emphasis upon federal works as a means of stabilization. Many devices have been suggested to get around this difficulty but until there has been a major reform or revision in the relations of federal, state and local governments and perhaps reform in the entire local and state governmental set-up, there is danger that rapid expansion in the use of federal powers would establish patterns that would cause a deterioration in local and state government for some years to come.¹⁴

VI. *Consumer Subsidies*

The difficulties mentioned above have led to the suggestion that a more appropriate means of supporting effective demand would be outright cash grants to the public in the event of any significant decline in effective demand.¹⁵ These grants would either replace unemployment insurance or supplement it but would also be made to employed workers as well. The basic consideration would be to pay out enough money to support effective demand at full employment levels. In a period of full employment or inflation, the process could be reversed and surplus cash receipts retained by the Treasury or used to reduce the debt in an anti-inflationary fashion.

Proposals of this type suffer from two defects. First, is the common problem of all stabilization plans—the problem of timing payments to meet the true needs of the situation. Second, is the possibility that the support of consumer demand would not be sufficient to prevent the continuation of a decline in investment activity in a free-market system. There is also the danger that the removal of the connection between eligibility for grants and personal contributions and obvious need would invite the abuse of the system and would tend to reduce incentives over the long run. It is strange, however, that this is generally considered a more radical proposal than the use of public works or make-

¹³ Henry C. Simons, *op. cit.*, pp. 13-14.

¹⁴ J. M. Clark suggests that increases in federal public works projects are not justified until stabilization of essential current services is provided for. J. M. Clark, *Economics of Planning Public Works* (Washington, 1935), p. 76.

work projects. In terms of its effect on the main features of the free-market system this approach is the least disturbing of all that are commonly considered to be at all practical. Consumer freedom of choice would be fully protected and private control of production would be retained.

VII. *Program Implementation*

Even if it is assumed that there is agreement as to the type and timing of variable expenditures, there still remains the problem of the execution of this policy within reasonable time limits. As the federal government is by far the most influential, a successful solution of the problem of implementation of policy at this level is essential if effective results are to be achieved. In the first place, inspection of the major items of the current and expected future budgets of the federal government reveals that noneconomic considerations or contractual commitments are responsible for the greatest part of the budget.¹⁶ However, noneconomic considerations do not remain stable and may change within a very short time, as has been seen recently in the rapid expansion of defense and foreign aid appropriations. Thus, the most careful planning of works appropriations or welfare assistance may have to be modified overnight due to a shift in some other item in the governmental budget. Prediction of trends in the political sphere is even more difficult than the economic. One may conclude, therefore, that there must be a very effective and sensitive control mechanism designed to adjust the various elements in the federal budget to meet unforeseen developments as they arise. This control agency or group of agencies must be able to operate quickly and without lengthy debate.

In spite of the progress that has been made in recent years, the federal governmental system that has responsibility for execution of policy is not designed to be used in this fashion. The basic principle of division of powers that was established by the Constitution has made coordination of the executive, legislative and judicial branches of government necessary for effective management of complex economic plans or controls exceedingly difficult or impossible. Within the executive branch, the situation is almost as bad. At least twenty-one departments or agencies are independently charged with the formulation of policy on expenditures.¹⁷ Within the Congress the evolution that has led to consideration of appropriation bills by separate committees has proved difficult to coordinate and more difficult to modify. The practice of passing authorizations for public projects well in advance of appropriations makes the effective use of fiscal policy even more difficult. The

¹⁶ See notes 6 and 11 above.

¹⁷ C. C. Abbott, *op. cit.*, pp. 150-51.

recent reorganization of the Congressional committee structure has been generally discounted on the basis of the record since its enactment. The most encouraging recent developments are the expansion of the role of the Bureau of the Budget and the creation of the Council of Economic Advisers to the President. Both agencies can do much to make sense out of the existing chaos but as their authority is derived entirely from the executive, either a weak President or a recalcitrant Congress can prevent the best program from being executed.

Effective programming of federal financial policy may be most difficult at the very time it is most necessary. This follows from the fact that the chances of having a President of one political party and a legislative majority of another party are greatest in periods of rapid change or periods of economic dislocation. It is obvious that from a practical viewpoint some extensive reforms are necessary.

VIII. *Need for a New Approach*

Preoccupation with short-run solutions to the problem of stabilization and the use of an aggregate approach has led to the neglect of the long-range implications and obvious limitations of expenditure variation over the business cycle. On the other hand, the most severe critics of government intervention have ignored the public demand for higher standards of government service, the strength of noneconomic forces increasing expenditures such as war and defense, and the necessity of government intervention on a positive basis to prevent waste and suffering in the event of either inflation or depression.

The weakness of the noninterventionist's approach is obvious, and the trend toward increased government outlays continues in spite of their efforts to stop it. Any objective consideration of the level of government service and standards of public facilities indicates the need for increased expenditures and confirms the judgment that the demands of the electorate are not going to diminish. War, preparation for war and defense expenditures, along with the strength of the American dream of equal opportunity for all without regard to birth, assure the continuation of the trend. The extreme advocates of economy can achieve their objectives only at the price of inadequate defense or the destruction of the ideal of progress toward equality of opportunity for all. Neither price is one that a true democracy can pay.

The danger is that emphasis on the goal of stability and immediate action to offset adverse effects of a depression will result in so rapid a growth and concentration of political power that the free-market system will be seriously damaged. This danger arises because an increase in government expenditures invites the exercise of political influence as a means of achieving economic advantage. Once started, the trend

is likely to continue until the whole process of production and distribution is dominated by politics rather than the play of the forces in the market.

It is one thing to advocate the use of counter-cyclical government expenditures when the normal level of government expenditures is a small fraction of the total national income. It is another matter when the level reaches twenty-five per cent or more and there is no sign of a downward trend. No policy can be adequately assessed without consideration of the setting in which it is to operate. Certainly what was true in 1933 no longer holds. It is essential, therefore, that those interested in devising a stabilization policy that will be effective in the current situation and still remain compatible with the continuance of a free economy must pay attention to the changes that have taken place since the advent of the New Deal, particularly the financial repercussions of World War II.

In spite of the forebodings suggested above, or perhaps because of them, it is clear that there is still need for an effective government stabilization policy free of the adverse effects outlined above or the failure of the free-market system will lead to such reaction that it will lose the confidence of the electorate and the majority of thoughtful students of political economy. It is therefore necessary for those who are critical of some of the suggestions made in the past to offer reasonable substitutes.

In the paragraphs that follow, two sets of suggestions are made as a basis for a positive program in the current situation. The short-run suggestions are offered because there is need for immediate action to stop the current inflation and to cope with the depression that is likely to be upon us before the longer-range suggestions have been worked out.

The long-run suggestions are designed to focus attention on considerations relevant to the future health of the free-market system and the preservation of a democratic political system. Specific proposals made are not all original and can without doubt be improved upon. In many cases, the passage of time will indicate the advisability of shifting some of the objectives as well as the means sought to achieve them. There is no question, however, that an increasing amount of attention must be paid to the long-range implications of alternate policies if a radical change in our system is to be prevented.

IX. Short-Run Policy

The main objective of a short-run program should be the halting of the current inflation and the minimization of the adverse effects of the anticipated postwar depression. Another period of depression as long and as severe as the depression of the 1930's would be disastrous. It is

assumed that the need for action will arise before many of the longer-range reforms suggested below can be put into effect.

The first line of defense should be the built-in-flexibility in government budgets that arises from fluctuating revenues and maintenance of reasonably stable governmental expenditures over the cycle. This requires the continuance of a progressive tax system if constant rates are to produce a net government cash surplus to help curb inflation and a net deficit requiring new money or credit issue to help support effective demand in the event of a depression. Real progress along these lines is possible if federal aid is given to the states and local governments to support their normal services without reduction in depression. At the outset of a depression, this approach would seem to be preferable to a federal works program. As the federal contributions to states and local governments would be financed by the expansion of money supply, the income effects would be the same as if the federal government were spending the money directly. The use of state and local governments to administer the funds would prevent concentration of political power. Ideally grants or loans should be made on the basis of a formula measuring need, resources, past expenditure, and business conditions.

The advantage of such a system would be the minimization of political influence and the assurance that areas in greatest distress would receive assistance above the average. This suggestion is one that could be adopted in a short time. No major reorganization of government would be required and no radical change in the activities of government would be involved. Private investors would not find that it threatened traditional areas of private investment and the selection of projects could follow the patterns of the past. Some would be good and others wasteful but the general level would probably be better than would result from the log-rolling that is involved in the selection of projects on a national scale in Congress.

The major difficulty would be the political opposition to the granting of federal funds to the states and localities without detailed control and without opportunity to assure that benefits went to the majority party. This is true, however, of most any reform that tries to prevent the abuse of political power and can be overcome if there is sufficient demand for it by leaders of public opinion.

The problem of reduction of federal grants in the event of boom or continued prosperity is also substantial. State and local governments are no more anxious to tax their residents than the federal government and in the event of a change in status that indicated a reduction in funds from federal sources and either a reduction in state and local expenditures or an increase in the aggregate revenue collections by these gov-

ernmental jurisdictions, political opposition might prevent the sort of balance over the cycle that is indicated. This suggestion also assumes that the federal government would not tend to expand levels of expenditure in the event of a boom and contract in the event of a depression. If this happened, there would be need for an offsetting variation in revenues that might not be achieved by the normal fluctuations resulting from changes in national income. Although one must conclude that there is no automatic formula that will assure the results desired, this seems to be the best line of attack at the moment. Certainly nothing will be accomplished unless there is a greater degree of discipline and responsibility on the part of government officials and legislatures than has been the custom in the past.

The current problem of inflation is so tied to the mistakes of the past, the expansion in debt and liquid assets during the war, the shortage of capital and durable consumers goods, and the international commitments of the country, that the immediate situation seems to indicate a secondary role for fiscal policy as usually conceived. Certainly there is no reason to fail to maintain a revenue surplus and to make an effort to reduce the surplus of funds seeking to purchase scarce factors but in this situation a surplus on government account may be offset by an increase in private credit, an increase in velocity of existing money or monetization of the government debt, or some combination of the three. If further expansion of credit and monetization of debt is to be prevented, debt management and the central bank policy of the Treasury and the Federal Reserve System must be made more effective without delay. The failure to follow such a policy is, in large measure, the result of the fear that any effective action would precipitate a depression. Certainly the record of the past supports this fear. The record also suggests, however, that there is danger that failure to restrict money and credit expansion will lead to continued inflation and an even more serious aftermath.

Other short-run reforms are necessary in the tax systems of all levels of government if the effect of taxation is not to distort the normal market decisions of the business community and the consumer. First on the agenda is the reform of the definition of taxable income. Extension of provisions for loss realization and averaging would do much to prevent the possibility of the income tax adversely affecting investment. Improvements in equity that would result would also help make the tax more tolerable to the average citizen and the punitive features less marked. Full taxation of capital gains and allowance for losses with some averaging or step scale to allow for assets held over one year, is recommended as a means of both increasing the equity of the system and adding to the counter cyclical variability of the tax system. Closing the

tax exemption loophole would also do much to prevent the magnification of tax considerations in investment decisions. After these problems had been met, it might then be possible to tackle the problem of the double taxation of corporate income or at least reduce the level of the corporate tax.

At the state and local level there is equally great need for reform. Most states have a hodgepodge of taxes and the dependence of the local governments on the property tax has led to a continued weakening of their financial position and an increase in their dependence on state and federal governments for support. As a temporary expedient it is suggested that more attention be given to the possibility of state administered but locally assessed taxes.

Finally, the basis for meeting the expected crisis in employment and human welfare that seems least destructive is to expand the provisions for unemployment insurance in the event of need. The effectiveness of such grants can be improved greatly if the minimum levels of the poorer states are raised and the duration of the benefits are increased. The advantage of insurance is that the consumer still chooses the way in which he will spend his money and a minimum of political influence is involved.

It is still possible that the short-run suggestions made above will not be adequate to do the job. If this should be the case, the necessity of federal intervention on a larger scale would be clear and the decision as to the means to be used could best be made at that time. Both a work relief and a public works program are certainly in order in this event and there is nothing to be said against using both at the same time. If this is done, the standards for the larger public works projects might be maintained at a higher level and the prospect of establishing patterns of danger for the future minimized. Certainly the general reaction against many of the work relief activities in the 1930's served the useful purpose of hastening the reduction in government projects. The main point, however, is that the use of work relief or public works is not to be recommended at the outset and cannot be justified until there has been a full exploitation of other remedies.

The author is frankly not too optimistic over the possibility of achieving substantial stability in the short run. There seems to be no formula that will achieve this objective without a much greater concentration of power in the hands of the federal government than is compatible with the preservation of an economy that resembles the one we have enjoyed in the past. It is possible, however, that the effects of fluctuations can be tempered so that there will be time to institute more fundamental reforms correcting the basic reasons for fluctuations.

X. *Long-Run Policy*

Two long-run objectives are set forth as the most important in the current situation. First is the correction of the basic weaknesses of the system that cause or aggravate instability. Second, is the revision of governmental structure and procedure so that the performance of governmental functions can be efficient, decentralized and effectively controlled in a fashion compatible with the maintenance of stability and a free economy.

A detailed discussion of the first objective lies beyond the scope of this paper but there is general agreement that substantial progress in this direction depends on reform of the monetary and credit system, and the freeing of markets from the dominance of monopolistic restraints. Pursuit of these reforms raises the question of the extent of government *vs.* private control of credit and banking facilities, the possibility of achieving international monetary and trade reform in face of intense political rivalry, the question of labor-management relations, patent policy, wage-price policy, corporation and public utility regulation, and so on. The issue of monopoly is particularly important because the concentration of economic power in the hands of a few large corporations may well lead to the dominance of government by business even under the most favorable conditions with regard to stability. There is little to choose between this result and the dominance of business by government, but on the whole it would seem to be more distasteful.

The chances of achieving fundamental economic reforms will be improved if a long-range policy of governmental reform is instituted. A weak and divided government is not going to be successful in economic reform. Hope for rapid progress in this direction would seem to be greatly enhanced if much greater attention were directed to these issues, alternate programs discussed and a concerted effort to capture the support of leaders of public opinion were made. Certainly continuance of a makeshift system of government can only lead to difficulties as its significance increases.

In view of the position of the federal government at the present time attention must be directed first to the improvement in the operation of federal financial agencies and the coordination of the legislative and executive branches of government. A reasonable fiscal policy and expenditure control cannot be achieved by the present haphazard structure with its divided authority and lack of professional standards. If financial health is to be preserved and rapid adjustment to changing circumstances made possible, there is need for greater coordination of normal budgetary controls and monetary, credit, and banking controls than has been achieved to date. This requires the creation of a new agency

with responsibility for this work and the subordination of the Federal Reserve and Treasury as they exist today. The Bureau of the Budget has been suggested as the agency to do this job but it is not endowed with sufficient power to be effective. The ideal would be to create an authority given wide discretionary power but responsible to the Congress for the maintenance of certain basic conditions, such as the stability of price level. Preferably this agency would *not* be charged with the administration or preparation of detailed plans or programs needed in the event of depression. Its services would be used but if in spite of its effort there should be a need for more drastic measures, it would be better to have the authority for such a program given to a temporary agency which would see its job as a short-run affair. The reason for this suggestion is a desire to avoid pressure on the permanent agency to compromise its long-range program as the result of temporary changes in economic conditions.

Progress along these lines or other alternate programs that would hold out hope of improved fiscal policy is dependent upon the radical revision of the narrow view of the typical congressman. The inability of the average legislator to take a long view is largely the result of pressures brought to bear on him by his constituents and their ignorance of general economic policy but is actively supported by the committee system and the lack of effective party leadership on issues of broad economic policy, except for short periods. Detailed analysis of these issues would require another paper or a sizeable monograph but the immediate need for correction of these deficiencies must be established and greater interest taken by those who are concerned with economic policy as well as those concerned with political affairs.

The obvious need for better economic intelligence work on the part of the government must not be neglected. The improvement in this regard has been substantial in recent years but there is still much yet to be done. Some investment in the preparation of detailed plans of alternate programs to meet hypothetical situations would also prove to be desirable. A running inventory of the state of the nation's economy should be maintained at all times. The possibilities of prediction of major economic trends should be fully explored. An investment in a determined effort to predict economic trends by statistical methods might not pay off but it is only the federal government that can undertake such a program, and the rewards that would accrue as a result of even limited success would fully justify the gamble.

In the area of state and local governments, even greater need of reform of governmental structure exists. The existing pattern of political boundaries, established by accident or to meet conditions no longer

present, prevents the efficient discharge of governmental services in many areas and has left the financial structure of state and local government in an intolerable condition. The result has been bad government and government finance at the local and state level, the growth of reliance on the federal government for more and more assistance, and the direct assumption of responsibility by the federal government for jobs that should be done at other levels. As a consequence, little possibility of a coordinated attack on the major problems of the country by all governmental levels exists today.

Perhaps the best remedy would be the complete scrapping of all state and local governmental jurisdictions as presently constituted and the reorganization of governmental units of a size and covering an area that represents an efficient administrative unit. The obvious impossibility of achieving any reform of such a drastic nature suggests that new agencies be established to coordinate or assume many of the functions of the local governments. Political and social loyalties could remain in the original jurisdiction but the main job of government at the local level could be transferred to more effective units. This suggestion is subject to the criticism that even greater confusion would result from the multiplication of governmental organizations but the success of such a device in the case of the TVA and the Port of New York Authority gives hope that substantial progress can be achieved. Failure to act will have repercussions that are certain to be more troublesome as time goes on.

Finally, there is need for a revision of the objectives of the average citizen and the average business leader. The exclusive concentration of the average man on his business, locality and personal economic affairs must be changed if many of the reforms suggested can be put into operation. How this may be done is the question. One of the best means is leadership on the part of governmental officials, legislators, and businessmen. The first step should be an all-out effort to improve the calibre of men in high office and their education in the major issues of the day. Propaganda cannot do the job but constant reiteration of the major issues yet to be faced will help raise the level of public interest and encourage better thought and action.

The advances in international trade policy in recent years and the widespread support of a more realistic international policy by large segments of the business community are signs that progress can be made. An agency that holds out hope for the future is the Committee for Economic Development which has sought to promote understanding and to develop a consensus rather than the promotion of a narrow business view. Education in economic affairs cannot start too early nor

FEDERAL RESERVE POLICY AND THE FEDERAL DEBT*

By LESTER V. CHANDLER

It is common knowledge that monetary management in this country has for several years been strongly influenced, if not dominated, by considerations related to management of the federal debt. With this debt amounting to more than \$250 billion and comprising about 60 per cent of all outstanding debt in the country, the foremost objective of our monetary policy has come to be "the maintenance of an orderly market in government securities" and the prevention, or at least a limitation, of the rise of yields on these securities, especially on the long-term issues. Though the rise of this new objective has been the subject of widespread discussion, the writer believes that its full implications are not generally appreciated. The purpose of this article, therefore, is to trace the rise of this policy objective and to raise some questions concerning its consequences.

The Evolution of the Policy before Pearl Harbor

Prior to 1937 Federal Reserve purchases and sales of government securities were primarily for the purpose of influencing the volume of member bank reserves and of member bank borrowings at the Reserve Banks. These were, of course, designed to affect interest rates, including yields on governments, but the effects were expected to result mainly from changes in the ability and willingness of banks to lend and purchase securities. But in 1937, apparently for the first time as a major policy objective, the Federal Reserve bought long-term governments for the purpose of limiting their price decline. After reaching high levels in late 1936, the prices of long-term governments and high-grade corporate bonds began to fall early in 1937. This decline did not extend to Treasury bills and notes. The Reserve System thereupon initiated what it called its "flexible portfolio policy," purchasing more than \$200 million of the longer-term bonds and reducing its holdings of the shorter-term notes and bills by about \$150 millions. The decline of government bond prices was stopped and reversed.¹ By such operations the System influenced directly—not merely through its effects on bank

*This material will become part of a broader study of the process of inflation in the United States since 1939, a study which the writer could not have undertaken without generous financial assistance from the Merrill Foundation For Advancement of Financial Knowledge, Inc. The author is professor of economics at Amherst College.

¹ Board of Governors, *Annual Report*, 1937, pp. 5-7.

reserves—the yields on both long- and short-term government securities and indirectly the yields on others.

The avowed purpose of this policy was (1) to exert an influence toward orderly conditions in the money market, and (2) to facilitate the orderly adjustment of member banks to the increased reserve requirements effective May 1, 1937.² In justifying its policy the Board said,

In recent years the bond market has become a much more important segment of the open money market, and banks, particularly money-market banks, to an increasing extent use their bond portfolios as a means of adjusting their cash position to meet demands made upon them. At times when the demands increase they tend to reduce their bond portfolios and at times when surplus funds are large they are likely to expand them. Since prices of long-term bonds are subject to wider fluctuations than those of short-term obligations, the increased importance of bonds as a medium of investment for idle bank funds makes the maintenance of stable conditions in the bond market an important concern of banking administration.³

The System continued its flexible portfolio policy from early 1937 until after Pearl Harbor, though no extensive operations were necessary in 1938 and early 1939.⁴ Its next major operation in governments occurred in September, 1939, when the outbreak of war in Europe led to a sharp decline of bond prices. To stop this decline the System did two things: (1) It announced that all the Reserve Banks stood ready to lend on government securities at par value to non-member as well as member banks, the discount rate to be the one applicable to such loans to member banks. The rate at New York and Boston was 1 per cent, and five other Reserve Banks instituted a preferential 1 per cent rate on loans secured by governments. (2) It purchased nearly \$500 million of bonds in the open market. The Board justified these stabilizing purchases on two principal grounds: (1) To "exert a steadying influence on the capital market, which is an essential part of the country's economic machinery, and disorganization in which would be a serious obstacle to the progress of economic-recovery," and (2) to safeguard the large United States government portfolio of the member banks from "unnecessarily wide and violent fluctuations in price."⁵

At only one other time between late 1939 and Pearl Harbor did the Federal Reserve find it necessary to purchase governments to cushion

² *Ibid.*, p. 6.

³ *Ibid.*, p. 7.

⁴ For evidence that the Federal Open Market Committee continued to be concerned with maintaining an orderly market in governments, see Board of Governors, *Annual Report*, 1938, pp. 77-79. In the early part of 1939 the System allowed its holdings of Treasury bills to decline markedly because they could be replaced only on a virtually no-yield basis. By the end of the year it held no bills.

⁵ Board of Governors, *Annual Report*, 1939, p. 5.

a decline of their prices. This was in the spring of 1940, following the invasion of Norway and Denmark and later the Low Countries, when bond prices began to decline and the Reserve System added somewhat to its holdings.⁶ During the rest of 1940 the System decreased its holdings of long-term governments by about \$300 million, thereby retarding the rise of bond prices that occurred as outside demand recovered strongly, partly because of large additions to bank reserves resulting from voluminous gold inflows. The Reserve Banks maintained their holdings of governments practically stable during 1941 until the price break following Pearl Harbor, at which time they bought \$60 million of bonds and \$10 million of bills.

In summary, by the time the United States entered World War II the "maintenance of an orderly market for government securities" had already become an important consideration in Federal Reserve policy. The Reserve System was buying and selling governments to protect member banks against "unnecessarily wide and violent fluctuations" in the prices of the government securities that they held; to exert an indirect influence on other interest rates in the market; and to remove obstacles to economic recovery. It had not yet, however, reached the point of "pegging" government prices at stated levels and standing ready to buy all these securities offered to it at the pegged prices. In other words, it was maintaining an "orderly market for governments" in the sense of preventing "disorderly" changes in their prices and yields, but it was not yet maintaining a rigid yield pattern.

Federal Reserve Policy During the War

Upon our entrance into the war, the maintenance of an "orderly market for government securities" at low interest rates became not merely an important objective, but the clearly dominant objective, of Federal Reserve Policy. The Board of Governors assured the public on December 8, 1941 that the Federal Reserve could and would see that the Treasury was supplied with all the money that it needed for war finance.

The existing supply of funds and of bank reserves is fully adequate to meet all present and prospective needs of the Government and of private activity. The Federal Reserve System has powers to add to these resources to whatever extent may be required in the future.

The System is prepared to use its powers to assure that an ample supply of funds is available at all times for financing the war effort and to exert its influence toward maintaining conditions in the United States Government security market that are satisfactory from the standpoint of the Government's requirements.⁷

⁶ Board of Governors, *Annual Report*, 1940, pp. 3-4.

⁷ Board of Governors, *Annual Report*, 1941, p. 1.

This promise was amply fulfilled. The war effort may at times have been impeded by other shortages, but it never suffered from a lack of money. Thanks to a highly liberal Federal Reserve policy, the Treasury could get from the Reserve Banks or from commercial banks any funds that it needed beyond those secured by taxation and by borrowing from non-bank sources. Of the \$230 billion increase of the federal debt from June, 1940 to December, 1945, nearly \$75 billion was taken by commercial banks and \$22 billion by the Reserve Banks.

Moreover, a generous Federal Reserve policy enabled the Treasury to borrow these tremendous sums of money at low and slightly declining rates of interest. At the time of our entrance into the war the excess reserves of member banks amounted to nearly \$7 billion, and during the preceding five years they had only rarely been less than \$2 billion. Under these conditions and with a shrunken demand for investable funds, the whole structure of interest rates had fallen to low levels, and rates on safe short-term paper were low indeed. This situation was continued throughout the war period. In March, 1942 the Federal Open Market Committee agreed with the Treasury that the general market for governments "should be maintained on about the then existing curve of rates (but that this did not mean special support for issues which might be out of line or that any issue must be held at par or at any other fixed price)."⁸ The pattern of pegged rates above which market yields were not permitted to rise until well after the end of the war was $\frac{3}{8}$ of 1 per cent on 90-day Treasury bills, $\frac{7}{8}$ of 1 per cent on 12-month certificates of indebtedness, and higher rates on longer-term issues ranging up to $2\frac{1}{2}$ per cent on the longest-term taxable bonds.

The Federal Reserve helped maintain this pattern of low yields on governments in two principal ways.⁹ First, but less important, was the maintenance of low discount rates. The Reserve Banks stood ready to make advances at a discount rate of 1 per cent to both member and non-member banks up to the full par value of any government security offered as collateral, and they established a preferential rate of $\frac{1}{2}$ of 1 per cent on advances to member banks secured by governments maturing or callable within a year. Since the member banks owned an ample volume of the shorter-maturity issues, only the $\frac{1}{2}$ of 1 per cent rate was significant in most cases. This willingness of the Federal Reserve

⁸ Board of Governors, *Annual Report*, 1942, p. 104. See also pp. 12 and 106.

⁹ We need not deal at length with the lowering of reserve requirements of central reserve city banks from 26 to 20 per cent in 1942, the exemption of War Loan Deposit Accounts from member bank reserve requirements and FDIC assessments beginning in 1943, and the 1942 legislation authorizing the Federal Reserve to purchase securities directly from the Treasury but limiting such holdings at any one time to \$5 billion,

to lend at low interest rates was reassuring to some banks, but few of them found it necessary or desirable to take advantage of the opportunity. Banks needing funds could secure them more cheaply by selling low-yield Treasury bills to the Reserve Banks. Federal Reserve discount rates had already become largely meaningless.

The much more important method of preventing yields on government securities from rising above the pattern agreed upon with the Treasury was Federal Reserve open-market operations. The System relinquished its initiative and its accuracy of control over the volume of governments that it held in order to prevent yields from rising above the established pattern. The loss of initiative by the Federal Reserve was most obvious in the case of Treasury bills. On April 30, 1942, the Federal Open Market Committee ordered the Reserve Banks to buy all Treasury bills offered to them at $\frac{3}{8}$ of 1 per cent yield. And in October of that year it ordered the Reserve Banks to grant repurchase options to sellers of bills, permitting them to repurchase at $\frac{3}{8}$ of 1 per cent yield the bills that they had sold to the Reserve Banks. In this way the yield on Treasury bills was held constant until mid-1947. Moreover, Treasury bills were made as safe and liquid as money itself so the banks had no reason to hold large excess reserves. In a similar way, the Federal Reserve stood ready to buy all 12-month certificates of indebtedness offered to it at its $\frac{7}{8}$ of 1 per cent posted buying rate. Though no rates on longer-term issues were formally posted and publicized, the Federal Reserve nevertheless purchased these issues in whatever quantities were necessary to prevent their yields from rising above the established pattern, and it sometimes sold them as their yields fell below the pattern levels. Thus the Federal Reserve lost almost completely its initiative in open-market operations; its holdings of governments were determined by the Treasury as issuer of the securities and by other institutions and persons as buyers and sellers of them. It had to monetize all the outstanding governments that others were not willing to buy and hold at the established pattern of rates.¹⁰

As mentioned earlier, the pattern of yields on governments agreed upon by the Federal Reserve and the Treasury reflected, in general,

¹⁰ The London *Economist* (August 4, 1945), pp. 161-62, has argued that the loss of initiative by central banks originated not during the war but during the Great Depression when central banks initiated easy-money policies. They could assure the continuance of cheap money only by standing ready to supply all the money that the public elected to hold at low interest rates. This is in a sense true, but the cheap-money policy of the depression period was initiated to encourage general business recovery and could presumably be reversed if spendings approached a dangerously high level. We shall see later that an easy-money policy aimed primarily at holding down interest costs to the Treasury and protecting bondholders against loss in terms of money may lack this element of reversibility.

the pattern prevailing in the market in the early part of 1942. The principal exception related to 90-day Treasury bills, whose yield averaged less than 0.30 per cent in April, 1942 and which were pegged at the higher level of 0.375 per cent at the end of that month. It developed later that the short-term Treasury bills with their $\frac{3}{8}$ of 1 per cent rate and even the 12-month certificates with their $\frac{7}{8}$ of 1 per cent rate were less attractive to investors than the longer-term securities with yields up to $2\frac{1}{2}$ per cent. This trend became clear only after the end of 1942. During the first year of our participation in the war, Reserve Bank holdings of governments rose about \$3.7 billion, the increase being about equally distributed between the shorter-term bills and certificates on the one hand and the longer-term notes and bonds on the other. But during the remainder of the war and for some time thereafter, offerings to the Federal Reserve were composed almost entirely of bills and certificates. In fact, while its holdings of bills and certificates rose from \$1.9 billion at the end of 1942 to \$22.4 billion at the end of 1946, the Federal Reserve was able, owing to the strong outside demand for them, to reduce its holdings of the longer-term notes and bonds from \$4.1 billion to \$1.4 billion. And even so, the longer-term issues rose to a premium, the longest maturities reaching a peak premium of about 7 per cent and their yield declining to about 2.1 per cent in early 1946.

Though other factors contributed, the principal reason for this shift of investors' preferences toward the longer-term issues was undoubtedly the announced policy of the Treasury of not raising the interest rates to be carried by successive new issues and the Federal Reserve policy of preventing the prices of governments from falling below the pegged levels. In such a situation the conventional distinction between short and long maturities lost much of its meaning. So long as the Federal Reserve continued to support the prices of the longer-term issues, every one of them was perfectly liquid at the pegged price, as much so as the shortest-maturity Treasury bill. An investor could rationally prefer a shorter-term government with a low yield over a longer-term government with a higher yield only to the extent (1) that the longer-term issue was selling at a premium over the Federal Reserve support price and there was a risk that its price would decline, or (2) that the Federal Reserve would lower its support prices. In view of the fact that both official pronouncements and the problems of debt management strongly indicated that yields on the longer-term governments would be prevented from rising significantly not only during the war but also for an indefinite period thereafter, it is small wonder that the Federal Reserve as residual buyer came to hold a

large proportion of the shorter-term low-yield issues, thereby adding to bank reserves, while other investors bid down the yields on the longer-term issues.

*The Federal Reserve and Government Security Prices
Since the End of the War*

Remembering the history of its policy before World War II, and especially before 1937, one might have expected the Federal Reserve to abandon its easy-money policy and to quit supporting the prices of government securities on a low-yield basis as the Treasury ceased to be a net borrower and began to reduce its debt in 1946 and as inflation gained momentum. But no significant change of policy occurred until mid-1947.¹¹ Until this time the Federal Reserve continued virtually without change the wartime pattern of its support prices, though its officials repeatedly warned Congress that without additional powers they could not simultaneously continue to support government security prices and combat inflation effectively. The first departure from the pattern of yields maintained during the war came in July, 1947 when the Federal Open Market Committee eliminated the $\frac{3}{8}$ of 1 per cent posted rate on Treasury bills and announced that the yield on bills would thereafter be expected to find its proper position in the market relative to the rate on certificates, which continued to be pegged at $\frac{7}{8}$ of 1 per cent. The Committee emphasized, however, that the System would continue to purchase and hold bills to the extent necessary to maintain an orderly market.¹² The second departure from the wartime pattern came in August, 1947 when the Federal Open Market Committee discontinued its $\frac{7}{8}$ of 1 per cent buying rate on certificates and embarked on a policy of preventing yields from rising above the Treasury issuing rate on new certificates. The Treasury thereafter gradually raised the rate on newly issued certificates to 1- $\frac{1}{8}$ per cent. This permitted the yield on Treasury bills to move up to about 1 per cent. These levels prevailed until the late summer of 1948.

The third departure from the wartime pattern occurred in December, 1947 when the Federal Reserve lowered somewhat its support prices of longer-term governments. As already noted, the prices of these longer-term securities were considerably above par in 1946 and early 1947.

¹¹ It is true that the Federal Reserve in the spring of 1946 eliminated the right of non-member banks to borrow on government securities at the 1 per cent rate; that about the same time it eliminated the preferential rate of $\frac{1}{2}$ of 1 per cent on advances secured by governments maturing within a year; and that in the summer of 1946 it raised acceptance buying rates from $\frac{1}{2}$ of 1 per cent to 1 per cent. But for reasons that will be indicated later these actions were relatively ineffective.

¹² Board of Governors, *Annual Report*, 1947, p. 93.

In April, 1947 the average premium on taxable bonds with 15 or more years to maturity was about 4.6 per cent and the yield had declined to 2.19 per cent. Believing that these yields were too low, the Treasury sold between April and the end of October about \$1.8 billion of bonds out of its own investment accounts, and in October offered for sale a new issue of nonmarketable 2- $\frac{1}{2}$ per cent bonds.¹³ These sales, coupled with the rise of short-term rates, large flotations of corporate securities, and a general rise of the private demand for loan funds, caused the prices of long-term governments to fall and yields on the longest-term issues to rise to 2.37 per cent in November. The decline was apparently considered too rapid, for the Federal Reserve stepped in and increased its holdings of bonds by about \$2 billion during November and up to December 24. Then, the day before Christmas, the Federal Open Market Committee lowered its support prices for the longer-term issues. No government security was allowed to fall below par, however, and the Federal Reserve purchased vigorously to support the new pattern of prices.¹⁴

The fourth departure from the older yield pattern came in August, 1948 when the Secretary of the Treasury announced that on October 1 the rate on new certificates would be raised from 1- $\frac{1}{8}$ to 1- $\frac{1}{4}$ per cent.

Several aspects of these Federal Reserve and Treasury actions in 1947 and 1948 should be noted. (1) The structure of yields on governments was permitted to rise somewhat, the yields on short-term issues rising more than those on longer-terms. Between June, 1947 and October, 1948 the yield on bills rose from 0.375 to about 1.1 per cent, the yield on certificates from 0.875 to 1.25 per cent, and the yield on the longest-term bonds from 2.2 to 2.48 per cent. Yields on other comparable types of debt moved in a roughly parallel manner. (2) These actions indicate a shift of stabilizing operations away from short-term rates and toward long-term rates. From early 1942 until July, 1947, the Federal Reserve pegged the bill rate at the low level of 0.375 per cent

¹³ Federal Reserve Bank of Boston, *Monthly Review*, January, 1948, p. 7.

¹⁴ The Federal Open Market Committee's decision to take such action was arrived at in its meeting on December 9, 1947. Action was to be deferred until after the Treasury's January refunding operations had been completed unless market selling increased substantially. "It was understood that . . . the executive committee would continue the existing prices at which Government securities were being supported until after the Treasury January refunding had been completed, at which time prices of bonds should be permitted to decline rapidly, if the market did not support itself, to a level not more than 100- $\frac{1}{2}$ and not less than par on the longest restricted 2- $\frac{1}{2}$ per cent issue and to not less than par on 1- $\frac{1}{8}$ per cent one-year certificates. It was also understood that if, before the completion of the January refunding, market selling should increase substantially, the executive committee would be authorized to permit prices to decline to the level stated above as rapidly as was consistent with the maintenance of orderly market conditions." Board of Governors, *Annual Report*, 1947, p. 97.

with the result that the yields on long-term governments tended to be depressed below their 1942 levels. But the 1947-1948 actions show a tendency toward concentrating attention on preventing the longest-term rate from rising above 2- $\frac{1}{2}$ per cent while allowing shorter-term rates to rise relative to it. (3) These actions indicate some willingness of the Federal Reserve and the Treasury to reintroduce a degree of upward flexibility in interest rates. But the implications of these actions for the future must not be exaggerated. In the first place, they do not indicate that the Federal Reserve has abandoned its objective of "maintaining an orderly market for government securities" at low-yield levels. Both by its pronouncements and by its continued security purchases in the face of inflation, the Federal Reserve has indicated that the maintenance of government security prices is still a dominant policy objective. And in the second place, the fact that the Federal Reserve has allowed some rise of interest rates does not necessarily mean that it will permit further significant increases. This point will be amplified in later paragraphs.

Federal Reserve Support of Government Security Prices in the Future

Will the Federal Reserve in the foreseeable future abandon the support of government security prices and the maintenance of low yields as the dominant objective of its open-market operations in order to be free to combat inflation vigorously? All the available evidence indicates that this is highly unlikely with respect to the long-term governments, though future policy with regard to short-term issues is more uncertain. Several officials, including the chairman of the Board of Governors, the former chairman, and the president of the Federal Reserve Bank of New York, have stated emphatically their determination to prevent the long-term rate from rising above 2- $\frac{1}{2}$ per cent.

Typical of their statements is that of Marriner Eccles, former chairman, in December, 1947:

The one thing you cannot do is to have confidence shaken in that 2- $\frac{1}{2}$ percent rate. If you let that go below par, there is always a question, where does it go? Because people remember, a great many of them, what happened after the last war when they let those securities go below par.¹⁵

¹⁵ *Hearings Before the Joint Committee on the Economic Report*, December 10, 1947, p. 620. See also Eccles' statement in *Hearings Before the Joint Committee on the Economic Report*, April 13, 1948, p. 16. Chairman McCabe takes a similar position: "... I have a very strong conviction that it is vitally necessary to support the 2- $\frac{1}{2}$ per cent bonds. ... I would not say it is our policy forever. I say for the foreseeable future." *Hearings Before the House Banking and Currency Committee*, August 2, 1948, p. 101. For a concurring statement by President Sproul of the Federal Reserve Bank of New York, see *Hearings Before the Joint Committee on the Economic Report*, May 12, 1948, pp.

Though the Federal Reserve and the Treasury appear determined to prevent yields on the longest-term governments from rising above $2\frac{1}{2}$ per cent in the "foreseeable future," they appear less reluctant to allow the yields on short-term issues to rise above the levels prevailing in mid-1948, so long as the rise is not great enough to upset the market for long-term governments. Eccles stated in April, 1948,

I want to make another matter clear: We have never made the statement that we should support all Government securities at par. What we have said is that we should maintain the $2\frac{1}{2}$ percent rate on the long-term bonds. That should be the basic long-term rate.

The short rate should be permitted to fluctuate to the extent that it can be useful.¹⁶

President Sproul of the Federal Reserve Bank of New York agreed with this principle.¹⁷ In August, 1948 Eccles again argued the rate on certificates should be raised above $1\frac{1}{8}$ per cent, and seemed—though his statement was not clear on this point—to favor a gradual withdrawal of Federal Reserve support from short-term governments while firmly supporting the long-term issues.¹⁸ It seems very doubtful, however, that yields on Treasury bills and certificates can be raised very much above the levels attained by the autumn of 1948 without forcing the Federal Reserve to buy large quantities of long-term government bonds to prevent their yield from rising above $2\frac{1}{2}$ per cent. This is in line with Eccles' appraisal of the situation in April, 1948:

. . . Short-term rates probably cannot be raised much more without unsettling the $2\frac{1}{2}$ percent rate for long-term Treasury bonds.

When I say "cannot be raised much more," I am thinking in terms of an eighth of 1 per cent, to a maximum, say, of one-quarter. If you made the certificate rate $1\frac{1}{4}$ that would be raising it an eighth. If you raised it a full quarter, ultimately that would be $1\frac{3}{8}$. There may be, under certain conditions, a possibility of going as far as $1\frac{1}{2}$ in a short-term rate, but I certainly can't foresee that now.

101-2. Secretary of the Treasury Snyder stated, "I think we are definitely committed to a support of the $2\frac{1}{2}$ percent rate." See *Hearings Before the House Banking and Currency Committee on S. J. Res. 157*, August 4, 1948, p. 250.

Several specialists in the money market have pointed out to the writer that practically all the public statements of Federal Reserve officials have been to the effect that the long-term rate will not be allowed to rise above $2\frac{1}{2}$ per cent, not that the bonds will be supported at or above par. These observers believe that the distinction may be significant, for the Federal Reserve might contend that a bond price fractionally below par would still produce a yield of only "approximately $2\frac{1}{2}$ per cent."

¹⁶ *Hearings Before the Joint Committee on the Economic Report*, April 13, 1948, p. 16.

¹⁷ *Hearings Before the Joint Committee on the Economic Report*, May 12, 1948, p. 93.

¹⁸ *Hearings Before the House Banking and Currency Committee on S. J. Res. 157*, August 3, 1948, pp. 181-82.

Clearly you can't let the short-rate go up to a point where pressure on the long-term rates result, so you have to support the long-term market.¹⁹

Secretary Snyder had stated earlier that, "We feel there are very narrow limits in which you can consider increased interest rates."²⁰ Sproul, relying heavily on the argument that even the longest-term bonds are in effect demand obligations so long as their price is supported by the Federal Reserve, believes that there is somewhat more room to raise the short-term rates without upsetting the 2-½ per cent rate on the long-term obligations.²¹ But he would probably agree with Eccles that so long as the 2-½ per cent long-term rate is prevented from rising, short-term credit cannot be made expensive; it can only be made a little less cheap.

In summary, it appears that both Federal Reserve and Treasury officials have decided that for "the foreseeable future" they will not allow the yield on the longest-term governments to rise above 2-½ per cent and that yields on the shorter-term issues will not be allowed to rise to a point where they will endanger the stability of the long-term rate.

Federal Reserve and Treasury officials have offered many reasons for continuing to stabilize the yields on government securities at low levels despite the upward sweep of inflation. Among those most frequently advanced are the following: (1) Increased rates on the federal debt would add to the already large interest burden.²² They point out that with interest charges already amounting to about \$5 billion a year and averaging 2 per cent of the outstanding debt, every increase of one-half of a percentage point in the average rate would add about \$1.25 billion to federal interest costs. It is important to note here that the Treasury could follow either of two general lines of action if it were decided to terminate the policy of maintaining low interest rates. The first would be to refund at higher interest rates only the maturing debt, allowing the rest of the outstanding debt to decline in price. This would postpone the full increase of interest charges, but it would impose capital depreciation on banks, insurance companies, and other holders. The other line of action would be to refund the entire debt at whatever

¹⁹ *Hearings Before the Joint Committee on the Economic Report*, April 13, 1948, p. 18. Eccles later stated, "... so long as you hold the 2-½ per cent rate ... the range within which the short-term rate can rise would be within its present 1-⅓ and I would say possibly 1-½ per cent." *Hearings Before the House Banking and Currency Committee on S. J. Res. 157*, August 3, 1948, pp. 182-83.

²⁰ *Hearings Before the House Banking and Currency Committee*, November 25, 1947, p. 50.

²¹ *Hearings Before the Joint Committee on the Economic Report*, May 12, 1948, p. 93.

²² Board of Governors, *Annual Report*, 1945, pp. 5-6. *Hearings Before the House Banking and Currency Committee*, November 25, 1947, p. 50. *Hearings Before the Joint Committee on the Economics Report*, November 28, 1947, pp. 246-47.

rates of interest were required to prevent government securities from falling below par in the face of tightened credit conditions. Though this would protect holders against capital depreciation, it would immediately increase significantly the interest costs of the Treasury. Neither Federal Reserve nor Treasury officials seem willing to follow either course of action except to the limited extent of raising somewhat the shorter-term rates of interest. (2) Fluctuating prices and yields on governments would greatly complicate the Treasury's refunding operations—a serious matter with \$49 billion of the debt falling due within a year and nearly \$100 billion within five years.²³ (3) An increase of the yield on governments, which without an increase of coupon rates would mean a decline of their prices, would impose capital losses on financial institutions and other holders and might lead to panicky selling and loss of confidence in financial institutions.²⁴ Officials recall the drastic decline of bond prices in 1920 when the federal debt was only \$26 billion and point to the greater possibilities of panic now that the debt is ten times as large and represents about 60 per cent of all debt in the country. Eccles has stated that with the public debt as large as it is today a free market is out of the question if that is taken to mean an unmanaged, unsupported market. The real question cannot be whether yields shall be free or pegged; it must relate to the levels at which pegging will occur. "There is no natural level. . . ."²⁵ (4) A decline in the prices of marketable government securities might lead to wholesale redemptions of the nonmarketable savings bonds, which are in effect demand obligations. (5) A moderate rise of the yields on government securities would not be effective as an anti-inflation measure.²⁶ Federal Reserve officials have argued that a rise of rates so small that it would not greatly increase interest costs to the Treasury or cause serious capital losses to holders of bonds would not be a strongly restraining factor. (6) Low interest rates and generally easy credit eased the process of reconversion and will help to maintain high levels of employment and production.²⁷ As late as May, 1948 Sproul contended that allowing long-term governments to decline more than

fractionally below par would interfere with private flotations of loans and might have deleterious effects on production and employment.²⁸

Effects on the Functioning of the Economy

If, as seems likely but not certain, the Federal Reserve continues to stabilize the yields on government securities at low levels, refusing to let the longest-term rates rise above 2-½ per cent and limiting the rise of short-term rates to levels consistent with the longest-term rate, what effects will this have on the operation of the economy? The most obvious effect, of course, is to hold down interest charges on the federal debt, thereby limiting the amount of taxes that must be collected for this purpose; and to protect holders of government securities from capital losses in terms of money, though not in terms of purchasing power. These results are far from insignificant. But much more important, I believe, are the effects on monetary policy, the behavior of the money supply, and the cost and availability of funds for private investment and consumption purposes.

With the adoption of this policy, the functioning of the Federal Reserve has been radically altered. This is most apparent in the case of open-market operations. Traditionally, this was the one instrument over which the Federal Reserve had complete and accurate control; the System could buy or sell precisely that amount of securities which it considered appropriate in light of existing and prospective economic conditions. But under its present policy of stabilizing government prices according to a selected pattern it has lost almost completely its initiative and its accuracy of control over its holdings of governments. It must as residual buyer purchase all the governments that others are unwilling to hold at the selected pattern of support prices. It must (1) purchase them not only from commercial banks but also from all other types of holders, and (2) purchase them regardless of the purposes for which the sellers will use the money. These two points are so important that they will be developed further.

In the past it has ordinarily been expected that the Federal Reserve would affect the supply of money and loanable funds primarily through the commercial banking system. It was a system of "bankers' banks"; it lent primarily to commercial banks, and even its open-market operations were undertaken primarily to affect the volume of commercial bank reserves and lending power. But with this new policy of supporting the prices of governments regardless of the type of institution or person selling them, access to Federal Reserve credit is no longer limited to commercial banks, but also extends to savings banks, in-

²⁸ *Hearings Before the Joint Committee on the Economic Report*, May 12, 1948, pp. 101-2. See also his testimony on pp. 94-95.

insurance companies, many other types of financial institutions, nonfinancial corporations, and individuals. This might not have been an important change prior to 1933 when the federal debt was small, but as Table I suggests, it is of the greatest importance when the federal debt held outside the government and the Federal Reserve amounts to nearly \$200 billion and that held by nonbank investors amounts to more than \$130 billion. So long as the Federal Reserve follows its present policy all these institutions and persons are in a position to secure at their option very large amounts of additional

Total held outside the Federal Reserve and U. S. Government agencies and trust funds	197.4	38.9	158.5	507

^a *Federal Reserve Bulletin*, June, 1948, p. 700. This table includes not only marketable government issues that are directly supported, but also nonmarketable issues—principally savings bonds—which are not directly supported by the Federal Reserve. Even these, however, are indirectly supported, for the Treasury must redeem them on demand and—to the extent that its surplus and sales of nonmarketable issues are inadequate—refund them with marketable issues which are supported by the Federal Reserve.

money by selling their governments to the Reserve Banks at the support prices. And the decision as to the amount of new money to be issued in this way lies with the holders of securities, not with the Federal Reserve. The cost of this money is, of course, the yield sacrificed on the securities sold; it is an "opportunity cost." Thus, when the Federal Reserve changes the yield pattern on governments, it is in effect changing the cost of money to sellers of the securities.

Moreover, in pursuing its present policy the Federal Reserve cannot

refuse to buy and monetize governments even if it disapproves of the purpose for which the new money will be used. Holders may exchange their securities for money to be used for (1) consumption, (2) purchase or construction of capital goods, (3) repayment of debt, (4) purchase of other securities, new or old, or (5) increase of idle balances. The Federal Reserve is powerless to prevent monetization of the government debt at the selected pattern of interest rates even if the new money is used directly to inflate spendings for consumption or capital goods or is used to supply liberal low-cost loans for these purposes.

In short, we are now on what may be called a "low-yield government security standard," for the Federal Reserve stands ready to monetize all the debt that others are unwilling to hold at the selected pattern of yields. And the commercial banks can, of course, expand their credit by a multiple of any new reserves furnished to them by this process, just as they can in response to increases of the monetary gold stock.

This new policy has made Federal Reserve discount rates practically ineffective as they are raised above the level of the lowest yields on government securities held by member banks. For example, in mid-1946 the Reserve Banks discontinued the $\frac{1}{2}$ of 1 per cent preferential discount rate, so that their 1 per cent discount rate was the lowest one remaining. This had practically no effect on the credit situation, for commercial banks were holding more than \$1 billion of Treasury bills on which the yield was only 0.375 per cent, and about \$14 billion of other governments maturing within a year on which the highest yield was 0.875 per cent. The discount rate increases to $1\frac{1}{4}$ per cent in January, 1948 and to $1\frac{1}{2}$ per cent in August, 1948 were largely ineffective for similar reasons. In the autumn of that year banks held well over \$20 billion of governments maturing within a year and carrying a maximum yield of $1\frac{1}{4}$ per cent. Thus, discount rates below the yields on governments may tend to ease credit, but rates above the yields on governments which banks can sell freely to the Federal Reserve are likely to be largely meaningless. Even the "psychological effects" of rate advances above the yields on governments are likely to be insignificant when banks are largely out of debt to the Reserve Banks and know that they can remain so by selling governments at their own option.

Similarly, increases of Federal Reserve buying rates on acceptances are largely ineffective above the yield level on Treasury bills. Banks needing funds will sell Treasury bills rather than acceptances to secure needed funds, and they will shift from bills to acceptances whenever yields on acceptances rise significantly above the Treasury bill rate. The acceptance rate will continue to be of little importance,

however, so long as the volume of outstanding acceptances remains at a low level.

The Reserve System can still use "moral suasion," but this instrument, too, is seriously weakened by the fact that member banks are practically out of debt to the Reserve Banks and know that they can remain so while they have so many governments that they can sell to the Federal Reserve.

Even the efficacy of increasing member bank reserve requirements is seriously reduced by the Federal Reserve policy of buying governments freely at the sellers' option. By mid-1948 the Board of Governors had already raised member bank reserve requirements to almost the limit of their statutory authority; there remained only the power to raise requirements against demand deposits in central reserve cities from 24 to 26 per cent. In August, however, Congress gave the Board power to raise reserve requirements by an additional 4 percentage points against demand deposits and 1-½ percentage points against time and savings deposits. By using these powers to the full, the Federal Reserve could add about \$3.5 billion to the volume of reserves required against existing deposits with member banks. But it is far from certain that such a policy would either force a reduction of bank credit or curtail a rise, for member banks can easily replenish their reserves by selling some of their governments—of which they hold more than \$55 billion—to the Reserve Banks. An increase of reserve requirements can retard the expansion of bank credit for private purposes only to the extent that banks are reluctant to reduce their holdings of governments in order to acquire other assets. This point will be discussed more fully in a later section.

The Federal Reserve support program also alters the relationship of the Treasury to monetary controls. In the first place, the Treasury determines the coupon rates to be borne by its issues, so that while the Federal Reserve is committed to supporting governments at or near par the Treasury also determines within narrow limits the pattern of market yields. At times the Treasury has followed the advice of Federal Reserve officials, but at other times it has refused to do so and has insisted on maintaining lower interest rates than the Federal Reserve desired. Rumor has it that the Federal Reserve tried unsuccessfully during the war period to get the Treasury to raise yields on its shortest-term issues, and Eccles has testified that just after the war and again in early 1948 the Treasury refused to follow Federal Reserve recommendations that short-term rates be increased.²⁹ In the

²⁹ *Hearings Before the House Banking and Currency Committee on S. J. Res. 157*, August 3, 1948, pp. 187-88.

second place, the Treasury's taxation-spending policies affect the behavior of the money supply even while the Federal Reserve maintains a fixed yield pattern on governments. A fiscal policy that raises the propensity to save out of a given level of national income or that reduces the expected profitability of new investment tends to reduce the demand for bank credit and the creation of new money, while a fiscal policy that induces less national savings or that inhibits investment spendings less tends to increase the volume of new money created by the banking system. In the third place, the willingness of the Federal Reserve to buy governments at the sellers' option reduces greatly the anti-inflationary effect of Treasury redemptions of securities held by the Federal Reserve and commercial banks. When banks lose reserves as a result of Treasury retirement of Federal Reserve holdings, they can easily repair their reserve position by selling securities out of their own portfolios to the Reserve Banks. For example, it is estimated that during the first half of 1948 the Treasury retired \$4 billion of securities held by the Federal Reserve. This tended, in the first instance, to reduce bank reserves, but during the same period the Federal Reserve was forced to restore \$2.8 billion to bank reserves by purchasing governments in the market.³⁰ Treasury retirements of debt held by the Federal Reserve can tighten credit only to the extent that banks are reluctant to sell governments in order to repair their reserve position and acquire other assets.

We come now to a crucial question: To what extent, if any, can credit for private investment and consumption purposes become more costly and less freely available so long as the Federal Reserve continues its readiness to monetize the government debt at low interest rates and the entire community retains its freedom to shift funds at will among the various branches of the long- and short-term money market? Would even a further rise of the demand for loan funds and/or a further decline of the propensity to save tighten credit for private purposes? My judgment is (1) that the cost of private credit can rise in a roughly parallel manner to the increases in yields on governments produced by changes in Federal Reserve support levels, but

³⁰ This does not pretend to be a complete discussion of the effects of fiscal policy. Its purpose is merely to point out that with everyone free to sell securities to the Federal Reserve, the use to which the Treasury applies its surplus revenues is less important than it would be if banks and others did not have access to the Reserve Banks at their own option. A full discussion of the subject would have to discuss separately (1) the effects on private consumption, saving and investment resulting from collecting taxes in excess of government spendings, and (2) the effects of using the surplus (a) to build up Treasury balances in its own vaults, at the Federal Reserve, or at commercial banks, (b) to retire Federal Reserve-held debt, (c) to retire commercial bank held debt, and (d) to retire debt held by others.

(2) so long as "prosperity" continues, the cost of private credit cannot rise much *relative to* the yield on governments, and the availability of credit for private purposes cannot be lessened very much.

These conclusions are based on two general considerations: (1) The Federal Reserve maintains its yield pattern on governments at any given time by standing ready to issue money (and reserves to banks) in exchange for any government securities that others are not willing to hold at the pattern of yields. (2) All holders—institutional and individual—retain their freedom to shift their funds at will between government securities and all other types of assets in such a way as to equalize the marginal attractiveness of all types of assets. The differences that have prevailed between yields on various governments and other securities presumably measure the marginal estimate of differences in risk and liquidity. Several factors could permit yields on private securities to rise relative to those on governments: (1) A rise of the estimated risk and illiquidity of private securities relative to governments. This is not likely to be important while the inflation continues. (2) Inertia. Having already made up their portfolios, some investors may be slow to sell governments in order to purchase private securities whose yields have risen. (3) Specialization of financial institutions and individual investors. Since some investors specialize in holding certain types of securities, their funds do not flow freely into other branches of the money market. (4) Policies of "balanced portfolios" and diversification of types and maturities held. Strongly imbued with these ideas, many investors may hesitate to upset what they consider to be a balanced portfolio in order to shift to other securities. Commercial banks, with their present low ratio of capital accounts to total assets, may in some cases be reluctant to load themselves heavily with risky obligations. All these factors contribute to the immobility of funds among the various branches of the money market and might permit some tightening of credit for private purposes while yields on governments are held constant. The Federal Reserve was apparently relying largely on these "frictions" when it expressed hope that by increasing member bank reserve requirements it could tighten private credit somewhat without a significant rise in the yields on governments. But it is easy to overestimate the immobility of credit.

Several developments since the prewar period may have increased the mobility of funds from government securities into other branches of the money market. Among these are: (1) The large volume of government securities held by institutional and other investors. As mentioned earlier, investors in this country hold nearly \$200 billion of federal securities, an amount considerably in excess of all other outstanding debt obligations and equal to many times the annual net

increase of private debt. Even if the flow of current savings were very small and the demand for funds very high, investors as a group would have to sell only a small percentage of their governments to be able to absorb all new private issues during any year. The importance of this point is magnified by the fact that every net sale of governments to the Federal Reserve, whether by banks or others, adds an equivalent amount to member bank reserves and permits a multiple expansion of commercial bank loans and investments. (2) The widespread ownership of government securities. If most of the outstanding governments were owned by only a few types of financial institutions specializing in a few types of private credit, the mobility of funds out of governments and into the other branches of the money market might be quite restricted. But this is not the situation, as Table I shows. The mobility of credit would seem to be enhanced by the fact that virtually all types of institutional and individual investors who ordinarily lend in the various branches of the money market hold these large volumes of governments that they can sell to secure funds for lending. (3) The fact that investors' holdings of governments are so much larger, as a proportion of total assets as well as in absolute amounts, than they were in the prewar period. For example, government securities as a percentage of their total assets increased between 1939 and 1948 from 30 per cent to 62 per cent in mutual savings banks, from 40 per cent to 70 per cent in commercial banks, and from 27 per cent to nearly 50 per cent in life insurance companies. This tremendous growth in their government holdings—which in many cases occurred largely because of the scarcity of other debt obligations—should make for an increased willingness to shift out of governments and into other type of securities, for investors are likely to feel that they are now overly safe, overly liquid, and too dependent on government obligations.

We conclude, therefore, that though the immobility of credit among the various branches of the money market will probably permit some rise in the cost and some decrease in the availability of credit for private purposes even while yields on governments are pegged at a given level, credit is nevertheless a highly mobile commodity. Though its direct objective is to control yields on government securities, the Federal Reserve is effectively controlling, though less precisely, yields on outstanding and new issues of private debt obligations. It was, I believe, the late Lord Keynes who once bemoaned the fact that central banks, operating largely through discount rates and open-market operations designed to regulate the volume of commercial bank reserves, were unable to control with any accuracy long-term interest rates. He could not make such a complaint in the United States today, but he might not be happy to know that the Federal Reserve is using

this newly developed power to hold interest rates at low levels and to assure the easy availability of investible funds despite the onrush of inflation.

It is beyond the scope of this article to assess quantitatively the contribution that our low-interest, easy-money policy has made to the height and duration of inflation. Such an attempt would require, among other things, an estimate of the interest elasticity of private saving, private investment, and hoarding. A few relevant observations will, however, be made.

In the first place, the continued assurance of a liberal supply of loanable funds and money at low rates of interest which are kept stable or allowed to rise only within a very narrow range cannot fail to be an unstabilizing factor in an economy in which expectations concerning the marginal efficiency of capital fluctuate widely relative to the propensity to save. Such a policy is, of course, appropriate to a period when the marginal efficiency of capital is so low relative to the propensity to save that investment and saving are equalized at a level of national income so low as to produce widespread unemployment. But it is not appropriate to a period in which the marginal efficiency of capital is so high relative to the propensity to save that saving and investment can be equalized only at progressively higher inflationary levels of national income. To assure a liberal supply of credit at low interest rates in such a period is to say, in effect, that the inflation shall not be hindered by any increase in the cost or decrease in the availability of investible funds; despite any rise in the propensity to consume, despite any increase in public and private demands for funds for investment spendings, despite any increase in the demand for money for transactions purposes as price levels rise, the Federal Reserve stands ready to assure an ample supply of low-cost money by issuing new money itself and by providing commercial banks with additional reserves to support new monetary issues by them. The rate of investment spendings need not be limited to the amounts the community is willing to save out of a given level of national money income, for the Federal Reserve must under its present policy create, or provide reserves to permit the creation of, enough new money to meet the surplus demand.

Such a policy seems beautifully designed to sustain continued inflation in an economy in which all the major groups—workers, farmers, and business enterprises—attempt to maintain their real purchasing power at levels exceeding the available supply of goods and services by demanding increases of their money incomes to offset, or more than offset, each rise of prices. Economists have generally condemned as unstabilizing in its effects the Federal Reserve policy, enunciated in

the early nineteen-twenties, of "accommodating industry, agriculture, and commerce" at relatively stable rates of interest. But the present Federal Reserve policy of stabilizing yields on government securities at low levels produces comparable results. With demand uncontrolled, the Federal Reserve can stabilize interest rates at low levels only at the cost of losing control over the money supply.

In the second place, I believe that the inflationary contribution of the present Federal Reserve policy is underestimated by those who concentrate their attention on interest rates rather than on the supply and availability of investible funds. Some appear to contend that low interest rates do not make much of a contribution to inflation, for they do not increase very much either the propensity to consume or the inducement to invest. I believe that this analysis is not correct. It seems to assume that the market for investible funds is perfectly competitive, with the supply of investible funds being rationed solely through increases and decreases of interest rates which are highly sensitive. It would be more realistic to recognize that many interest rates are relatively sluggish and that much of the rationing of credit is effected by non-price methods, such as the lender talking the borrower into taking a smaller or larger amount of credit than he asked for, the lender regretfully informing the borrower, "Sorry, but I'm loaned up," tightening or relaxing standards of creditworthiness, refusal to underwrite a new security issue because "the present market is too tight," and so on. A tight money policy by the Federal Reserve can have a much more restrictive effect on private investment and on consumer borrowing than would be expected from a somewhat sluggish upward movement of the interest rate structure as the supply of investible funds is restricted. Conversely, the present easy money policy of the Federal Reserve probably enhances inflation more by assuring a highly ample supply and availability of loan funds than by maintaining interest rates at low depression levels.

Conclusions

Without attempting a full analysis of our war finance program, I should like to conclude with a few comments on the Federal Reserve's support program since the end of the war. In the first place, it is impossible to evaluate Federal Reserve policy without considering as well the attitudes and policies of the Treasury and Congress. Federal Reserve officials probably share the general fear of initiating policies that might prove to be too restrictive and that might precipitate the economy into deflation, but they seem to have less of a bias toward liberal credit than do the Treasury and Congress. The Treasury has displayed an understandable but probably not justifiable determina-

tion to hold down interest costs on the federal debt, and Congress has both feared that "prosperity" would be brought to an end and refused to use its taxation-spending powers to halt the inflation. So long as fiscal policy plays such an important role in our economy and is so closely related to the functioning of the monetary system, it is probably to be expected that Federal Reserve authorities will try to cooperate with fiscal authorities and will be influenced by the attitudes of the executive and legislative departments. Most economists favor a co-ordination of fiscal and monetary policies, but they should recognize that recent experience emphasizes the difficulties of securing such coordination on a satisfactory basis. If Federal Reserve and fiscal authorities disagree, should the Federal Reserve insist on taking actions that would embarrass the fiscal authorities? Should the Treasury have veto or directive power over the Federal Reserve, or should the Federal Reserve have control over certain Treasury actions, such as determining interest rates on the federal debt? Should we establish an agency to coordinate fiscal and monetary policies? How can fiscal authorities be induced to pay more attention to the broad economic effects of their policies? To at least some extent, the unsatisfactory nature of our fiscal-monetary policy since the end of the war must be laid to the unsatisfactory division of authority between the Federal Reserve and those responsible for fiscal policy.

In the second place, it is important to distinguish between a policy of maintaining a rigid pattern of yields on government securities and a policy of merely maintaining an orderly market for governments. As pointed out earlier, a policy of maintaining a rigid yield pattern or of holding the fluctuations of yields within narrow limits is likely to be incompatible with the maintenance of economic stability; for the central bank can achieve stability of interest rates only by surrendering its control over the money supply. On the other hand, the maintenance of an orderly market in governments need not conflict with the objective of promoting economic stability if this is interpreted to mean that the Federal Reserve should buy and sell securities in such a way as to promote orderly adjustments of security prices and yields. For example, under such a policy the Federal Reserve might sell securities, or at least curtail its purchases, in order to establish higher yields but still prevent "disorderly" movements. Such a policy would be difficult to administer, however, and the Federal Reserve would have to choose between accuracy of its control over yield levels and accuracy of its control over the money supply.

In the third place, it is not at all clear just why Federal Reserve and Treasury officials have continued since the end of the war to peg yields on governments at low levels. Some of the frequently offered

justifications were given in an earlier section, but they may be rationalizations rather than motivating reasons. These seem to boil down to three principal arguments: (1) Higher interest rates would increase costs to the Treasury, (2) Higher yields without higher coupon rates would impose capital depreciation on institutional and individual holders of the government debt, and (3) Higher yield levels or the uncertainty attending the upward movement of yields, would increase the difficulty of private financing and might initiate a business recession. These arguments are of varying weight and may indicate differing policy decisions.

The argument that yields should be pegged at low levels to keep down the cost of government is unconvincing, even if all outstanding governments were immediately refunded at higher interest rates so that the full burden of increased interest costs would be felt at once. (a) It does not follow that minimizing interest costs tends to keep down the total cost of government. With interest costs making up only about one-eighth of the total costs of the federal government, total governmental costs may actually be increased if the low-interest policy enhances inflation significantly. (b) If it is felt that higher interest rates would be an "unjust" enrichment of the rentier class, the problem should be attacked through taxation rather than general credit policy. (c) Even if low interest rates do decrease total governmental costs, the avoidance of increased taxes for this purpose is less important than the promotion of economic stability. Interest costs are transfer rather than exhaustive payments, and the shifts of income involved in paying them out of higher tax collections are presumably less arbitrary than the shifts of wealth and income induced by inflation.

Also unconvincing is the argument that yields on governments should be pegged at low levels to protect holders of government securities against capital losses. (a) It is not clear that buyers of marketable government securities may properly ask for protection against a depreciation of their securities in terms of money. (b) The policy of preventing securities from depreciating in terms of money has not protected bondholders against loss of purchasing power. Many holders of the federal debt would probably be injured less by a decline in the monetary value of their bonds than by the loss of purchasing power induced by the continuance of easy-money. In general, it seems unwise to employ general credit policy to protect bondholders against capital losses in terms of money if this enhances inflation and reduces the purchasing power of all groups with relatively fixed money incomes. (c) It is not necessary to peg yields at low levels to protect holders of governments against capital losses in terms of money; the alternative is to refund the outstanding governments by issuing new securities with

coupon rates high enough to enable the securities to sell at par value in the face of the tightened credit conditions imposed by the Federal Reserve in the pursuance of its function of general economic stabilization. I am not convinced that the government is under any moral obligation to protect the holders of its obligations against capital losses in terms of money, but if this is to be our national policy it should be accomplished through appropriate adjustments of coupon rates rather than by having the Federal Reserve relinquish its control over the money supply in order to maintain a pattern of interest rates established by the Treasury at some time in the past. Such a policy would require that coupon rates on federal obligations be changed from time to time, perhaps frequently, and would probably be criticized by the Treasury, Congress and perhaps some investors who are accustomed to dealing in the conventional types of government securities. But policy should recognize that stability of bond prices, stability of coupon rates, and the maintenance of effective control over the money supply will at times be incompatible with each other in our economy. In my opinion it is of first importance that the Federal Reserve regain its freedom to control the money supply in the interest of economic stabilization, so that either the stability of government bond prices or the stability of coupon rates on those bonds should be sacrificed.

The third argument for continuing an extremely easy money policy since the end of the war—that higher yields would increase the difficulty of private financing and might initiate a business recession—is also unconvincing. It does have the merit of dealing with the objective, economic stabilization, that should be the primary concern of a central bank, but I do not believe that this objective would have indicated the assurance of an unlimited supply of low-cost money during the postwar period, and I suspect that Federal Reserve officials would not have thought so either if they had not been swayed by considerations related to holding down interest costs to the Treasury and protecting holders of government securities against capital depreciation. The Federal Reserve frequently tightened credit to halt overexpansions before the Great Depression, and it must have recognized that the slowing down of inflation during the postwar period required some restriction of private investment spendings so long as the propensity to consume remained high and government spendings for domestic and foreign purposes continued to be large. It is true, of course, that general credit restrictions are difficult to administer with precision and that they may not merely halt inflation but also precipitate a decline, but it does not follow that during a period of a high propensity to consume, large government spendings, and a very high marginal efficiency of capital

it is necessary to assure an unlimited supply of low-cost funds in order to avoid a cumulative decline of economic activity.

The growth of the federal debt to \$250 billion so that it equals one and a half times all other outstanding debt obligations does represent a marked change in our financial structure and gives rise to difficult problems of debt management. Yields on governments will probably continue for some time to dominate yields on private obligations. This, however, is no valid argument for maintaining an unvarying interest rate structure. A monetary policy aimed at securing economic stability requires control of the volume of investible funds, and with a widely varying demand this will sometimes mean variable interest rates. If, as a matter of national policy, we decide to continue protecting holders of governments against capital losses in terms of money, we should do so by varying the amount of interest paid to them, not by having the Reserve Banks passively monetize all the federal debt offered to them at a virtually invariable structure of interest rates.

THE LAW AND ECONOMICS OF BASING POINTS: APPRAISAL AND PROPOSALS

By J. M. CLARK*

Introduction

A crucial step toward clarifying the present state of the law is to distinguish two central issues: that of the non-base mill charging "phantom freight," appearing most clearly when there is a single basing point; and that of freight absorption by base mills, which would appear in isolation if every mill were a base mill.¹ The glucose cases dealt with the first issue and explicitly reserved the second. The cement case was argued mainly on the second issue.

In the issue of the non-base mill, the writer has reservations as to the legal reasoning used to deal with it in the glucose cases, but agrees with the probable economic result, assuming that reasonable latitude is afforded for differences between different mill or base prices, and for competitive freight absorption. As to freight absorption, he dissents (as will appear) from the legal reasoning on which Mr. Justice Black chose to rest his interpretation of the Robinson-Patman Act in the cement case, and sees objections to the resulting situation. These include not only serious uncertainty as to what the law requires, but inherent difficulty of clarifying it in a way that would avoid dangers of unduly rigid interpretation and enforcement, bringing unforeseen consequences, and likely to entail costs out of proportion to probable benefits. Objections apply also to law-making power exercised by the Federal Trade Commission, without proper accountability for the risky legal and economic doctrines it is free to employ.

*The author's past connections with the basing point question (now all terminated) include participation in the NRA study of iron and steel basing point pricing. Subsequently, he was engaged with Professor A. R. Burns to make an impartial report on the pricing system in cement, final completion of which was forestalled by the Federal Trade Commission's complaint against the cement industry, after which he consulted with counsel for the Cement Institute. He is aware of no present obstacles to his speaking with complete freedom, as an unattached individual.

¹The reader should note that I speak of "phantom freight" only with reference to that charged by a non-base mill at points that are nearer to it, freightwise, than they are to the base that governs the delivered price. "Freight absorption," as here used, refers to a base mill, reaching out to sell in areas where the delivered price is governed by another base; and the first mill must accept a mill net less than its own base price in order to sell there. So used, the terms have unambiguous meaning. As sometimes used, the distinction becomes clouded, because base prices at different bases may or may not be equal, and a non-base mill may or may not be regarded as the limiting case of a base mill with a base price so high as to be inoperative.

But he is seriously concerned that something should be attempted to make competitive pressures on prices stronger than they are under full-dress basing point pricing, with the appurtenances that commonly go with it. Therefore, he would be opposed to new legislation that would legalize such pricing as it has existed in the past. Some modifying legislation may be called for; but it should be approached with great caution not to destroy power of regulation, finally achieved in this field. The need may depend on the success with which the difficulties of clarification are met.

What is happening has the effect of regulation of trade practices. I believe this is not incidental to conspiracy, as Commission representatives maintain; but that allegations of conspiracy, including collusion inferred from similar acts, are mainly enabling instruments to validate orders changing trade practices. But probably neither the Commission nor the industries affected are eager for the Commission to take over the full responsibility and authority of positive administrative control in this field. So the method remains a hybrid, of the baffling sort in which years are spent arguing everything about the case except the effects (legal and economic) of the order that will finally be issued. During the basic litigation, economic considerations are elbowed out or distorted by legalistic exigencies, both sides probably producing about equally bad or irrelevant or one-sided economics. Since serious and realistic consideration of the effects of an order cannot begin until after the order is issued, economic analysis is backward, though the heart of legality in these cases is economic. This is unfortunate, but it seems to be the way our present system works.²

The Glucose Cases and the Non-Base Mill

In the glucose cases, the legal reasoning by which the decisions are supported appears fairly distinct from the real economic reason why the cases were decided as they were, which is barely indicated but not explicitly formulated. In terms of their legal reasoning, these cases seem to outlaw the non-base mill for the future, condemning the mill that has made no attempt to set up a *bona fide* base price of its own. A possible exception is the case of a mill which has had a base price,

²From the above, it is evident that my views meet one test of objectivity—they will satisfy neither side. After the strong presentation of the anti-basing-point case by Professor Frank A. Fetter and Mr. Corwin D. Edwards (in this *Review*, December, 1948, pp. 815-42) there is room for a contribution that would do something to redress the balance. This, and an invitation from the editor of this *Review*, have tempted me to enter the discussion, contrary to my former intention to stay out. But my views clearly disqualify me from presenting the basing point side of the case. If I advertised to do so, or were so advertised by others, it would be a fraud on the industries involved. The only reason for dwelling on this is that I have been so advertised in the past, when my views were essentially the same as now.

but has become a non-base mill through a reduction of the base prices of surrounding mills, to a point at which the first mill's base price no longer makes the delivered price to any destination.

One dubious legal argument, peculiar to these cases, seems not necessary to the decision reached. The Corn Products case involved a company owning a base mill at Chicago and also a non-base mill at Kansas City. In this situation, there was no defense of the non-base mill's pricing as being made "in good faith to meet an equally low price of a competitor." in the Staley case, involving an independently owned mill at Decatur, Illinois, it was held that it could not take advantage of the same defense (hereinafter called the "good-faith defense") because the price structure it was meeting—that of the company owning mills at Chicago and Kansas City—had been shown to be illegally discriminatory. Thus the Decatur mill was held to be discriminating in favor of points nearer freightwise to Chicago than to Decatur, without benefit of the good-faith defense; though the price structure it was meeting was held to be discriminatory only against points nearer freightwise to Kansas City than to Chicago. On a large part of its sales, the Decatur mill was meeting prices quite properly based on Chicago. And once the Kansas City mill became a base, this particular defect in the Decatur mill's defense would be cured for the whole area.

What would remain would be, first, the holding that this defense is available only to a mill that has shown deference to the *prima facie* case against price discrimination by setting up some *bona fide* mill price of its own. Second, if it did that, its freedom to absorb freight would be subject to the interpretation of the cement case.

As distinct from this legalistic reasoning, the real economic basis for the decisions seems to be implicit in the Court's acceptance of the idea that customers near the non-base mill are deprived of those natural advantages of geographical location to which they are entitled. This expresses the common man's sense of equity in this matter, and it seems highly probable that it accounts for the tight or strained construction put on the statutory provisions the Court had to rule on. The implications are not spelled out, but are pregnant. They assert, on behalf of the customer located near an isolated producer, a right to price treatment better than the minimum which competition, necessarily competition of relatively distant rivals, would of itself enforce in his behalf. This customer is, to a limited extent, at the discretion of the limited or partial "natural monopoly of location" held by the producer who has no closely adjacent competitors. The doctrine of "natural geographical advantages" seems to assert, in effect, that this limited natural monopoly of location is, like other natural monopolies, affected with a public interest. This, in connection with the Robinson-Patman Act, affords a

basis for an unconditional requirement that there must be some *bona fide* and substantial area of uniform mill-net pricing (or possibly, as suggested above, there must at least *have been* such an area).

This implies a limitation on the freedom of the isolated mill to choose its mill price or base price. It is not to be presumed that it must equal the mill price or base price of any one of its competitors, despite implications that might be drawn from language in the glucose cases which makes discrimination begin at the midpoint, freightwise, between two producers. Compulsory flat equality of mill prices would be one way of stultifying competition, as no economist needs to be told who is familiar with oligopoly theory; and it is not proper to infer that the Court intended to require it. One producer must be free to reduce his mill price without knowing that all others are legally required to follow suit instantly, and it would seem that he must be free to raise it on the same conditions. But he cannot safely raise it so high, relative to his surrounding competitors, that it covers only a nominal area, and would therefore appear as an evasion of the rule in these cases. This leaves the maximum allowable mill price indefinite, but indicates the kind of considerations that will sway the Court in ruling on the point.

This theory of affectation with a public interest appears, in principle, defensible, but might point to an undesired kind of regulation. If the glucose cases stood alone, or if freight absorption (as distinct from phantom freight) were still freely possible, they might lead to an interesting and novel type of hybrid, quasi-public-utility maximum-price control, with cost figures presented to sustain the burden of proof that would lie against any base price so high as to cover a suspiciously small area, and thus to be open to the charge of evading the principle of the glucose cases. Instances are conceivable, though perhaps exceptional, in which an economically serviceable plant, in order to make a fair return, might need all the income it could get from a price structure that would come close to that of a non-base mill.

But if the effect of the cement case is to abolish freight absorption or reduce it to a more or less negligible role, that will automatically set a more effective limit on relatively high base prices; and the potential venture into direct base-price control will not materialise. The hard-pressed mill which needs a high base price, plus very extensive freight absorption, would be debarred from this way of meeting its difficulties. The long-run effect of the glucose cases, then, is dependent on that of the cement case.

Freight Absorption: the Cement Case and Its Interpretation

Six points, made against "systematic" freight absorption, may be distinguished. (1) On the facts of the case, it has been used as an instrument of collusive action impairing competition in price; and the instru-

ment, so abused, should be barred. (2) Collusive or coercive tactics have in fact been used to implement and police it. (3) It is of such nature that such tactics are required to maintain it in effect. (4) It is "inherently monopolistic." (5) It is discriminatory under Section 2 of the Robinson-Patman Act, and on the facts of the case, the burden of proof under the good-faith defense has not been sustained. (6) The good-faith defense is not available to any general practice, but merely to the meeting of "individual competitive situations." Points (1), (2), and (5) hinge on the facts of the particular case, but the others are general; and the state of the law depends on how far these general contentions have been sustained and are now the law of the land.

Charges under the Robinson-Patman Act are general in that they do not expressly require a showing of collusive action; and point (6), which Mr. Justice Black upheld in the cement case, is perhaps the most general of all. Chief Justice Stone, in the Staley case, had said: "But it does not follow that respondents may never absorb freight. . . ." Mr. Justice Black, in the cement case, does not quite reverse this, but transforms it into a finding that it does follow that respondents may not continuously absorb freight. He holds that the glucose cases decided that the good-faith defense was not available to any basing point system; a single producer loses its benefit if he absorbs freight "constantly," and all lose it if each makes *some* freight-absorbing sales, since that is "evidence of the employment of the multiple basing point system—as a practice rather than to meet 'individual competitive situations.' " This, he says, applies even if there is no phantom freight, only freight absorption.³

Thus he supports his holding that the glucose cases control the cement case, despite Chief Justice Stone's reservation. This seems an unwarranted extension of Chief Justice Stone's remark about emphasizing individual situations, which is already satisfied by requiring verification of the particular price that is being met.

The effect of this ruling hinges on whether it is conditioned on an independent finding of collusive action, or whether, as seems likely, it makes freight absorption, if prevalent to the degree described, *in itself* evidence of such constructive collusion or common following of a practice as would forfeit the benefit of the good-faith defense.⁴ In the latter case, we now have the spectacle, strange in American law, of the legality of A's act being at the mercy of what B may independently do;

³ Federal Trade Commission *vs.* Cement Institute *et al.*, October term, 1947, nos. 23-34, separate print, pp. 37-40.

⁴ While Section 2 of the Robinson-Patman Act is not contingent on collusion, collusion would naturally forfeit the good-faith defense; and the Commission so framed its cement order, which the Court is here upholding, as to apply only to common action.

and of a right, in theory equally available to all, not only emasculated by procedural obstacles, but legally voided if all take advantage of it, even to a limited extent, and with or without joint action.⁵ In that case, it is my layman's conviction that this is bad law, perhaps of the kind which hard cases proverbially make. There is ground for holding that, without common action, freight absorption would be less precise. No sound ground has been established for holding that it would not still be general.

This theory of inferred common action robs of meaning the position frequently expressed on behalf of the Commission, that freight absorption is not *per se* illegal, because the Commission has dismissed cases in which there was basing point pricing but no showing of collusion. The point is: was this dismissal a mere exercise of discretionary leniency in cases it could win if it chose, under the doctrine of the cement case? Legality is one thing and discretionary leniency another.

But there is one feature of the glucose cases that clearly does not carry over to the issue of freight absorption. Discrimination, to be illegal, must be calculated to injure competition. The kind of injury held to exist in the glucose cases was that suffered by a candy-maker who had to pay more for his glucose than his competitors, because he was far from a base mill, though near a non-base mill. It is the kind of injury that results from "phantom freight" and not from freight-absorption under a multiple-base system. For "phantom freight" directly affects the relative prices paid by different customers in competition with one another, and freight absorption does not. If freight absorption, as such, injures competition, the injury is of a totally different sort from that held to exist in the glucose cases. Therefore, the ruling of the cement case, under the Robinson-Patman Act, rested not only on the glucose cases but on an independent holding that freight absorption impairs competition between the sellers (as distinct from that between the customers) through the "matching of prices" which it brings about, when systematically practiced.

It is interesting that the company is wrong if it meets a competitor's actual, but discriminatory, price; and if it meets a calculated price of the sort the base mill could make without discriminating (base price plus freight), then it is wrong again unless it takes pains enough to verify whether this price actually exists. Between the two rulings, the good-faith defense seems to be squeezed fairly flat. Professor Fetter attempts to eliminate it completely, this being necessary to his contention that the law now requires uniform f.o.b. mill pricing; and two of

⁵ The analogy of obstructing traffic by standing on the sidewalk, of which the same thing is true, does not present comparable interests or exposures.

his positions do substantial violence to historical fact.⁶ He treats Section 2(b) of the Robinson-Patman Act as a new provision, and states that it was ingeniously devised and "smuggled into the bill," by or on behalf of the basing point interests. The fact is that this subsection was an amended version of a provision of the Clayton Act of 1914 (as Fetter had himself stated five pages earlier).⁷ And the nature of the amendment was to burden the former exemption with such heavy procedural obstacles as to make it of extremely doubtful effect. It makes "discrimination" *prima facie* unlawful, and this has been held to include freight absorption. Under the good-faith defense, it puts the burden of proof on the industry to rebut this *prima facie* presumption, including the burden of proving "good-faith," and it makes the burden more exacting by substituting "an equally low price of a competitor" for the more general phrase, "to meet competition." If counsel for basing point interests devised this amendment to increase the protection of his clients, his sanity should be inquired into. It was this "smuggled" amendment that facilitated the throwing-out of the good-faith defense in the cases under consideration.

Another erroneous statement of material bearing on this subject is in connection with Fetter's argument that the *prima facie* case against discrimination could not be rebutted (not even if the statute says it can) by showing that it was done "to meet an equally low price" previously made by a competitor, "for this is always the motive of discrimination."⁸ The fact is that it is not always the motive. In the period when the Clayton Act of 1914 was being debated, the kind of geographical price discrimination that was fresh in the public mind was the kind of predatory local price-cutting brought out in the Standard Oil case of 1911, through which independents were ruined by locally concentrated price-cutting that did not stop with meeting their prices, but was aggressive in setting prices below theirs, and which they could not meet. The imposing of "punitive bases," alleged in the cement case, is essentially similar, indicating that this issue is not exclusively ancient history. It is this kind of aggressive discrimination, not covered by the good-faith defense, which the clause was most clearly intended to prohibit.

⁶ I take this occasion to express publicly my sincere congratulations to Professor Fetter on what is in considerable part a well and valiantly earned personal triumph in an attack on a far-from-perfect condition. It has been a matter of personal regret that I was forced to disagree with so much of his argument and his concept of the desired remedy; mixed with intellectual enjoyment of a very pretty clash between incompatible concepts of method.

⁷ F. A. Fetter, "Exit Basing Point Pricing," *Am. Econ. Rev.*, Vol XXXVIII, No. 5, Dec., 1948, pp. 816, 821.

⁸ Fetter, *op. cit.*, p. 822.

It prohibited (predatory) beating of the other's price, and exempted meeting it. With only a procedural change in the statute, it is now construed to prohibit meeting (if sufficiently prevalent) while occasional beating of the other's price reduces the legal danger. What made the inversion? Simply the Commission's theory of what impairs competition, plus its theory of inferred common action. These theories make the law. Such latitude, alarming as it is to a lawyer, is needed, because impairment of competition cannot be defined by mechanical rules describing the form of a trade practice. But the process now in effect lacks essentials of "due process" appropriate to such powerful Commission law-making.

The issue is interestingly complicated by one further consideration. If, in this type of industry, there had been found leading cases—admittedly unlikely—in which producers generally and voluntarily followed uniform mill pricing, I am sure that the resulting division of selling areas among producers, plus sporadic high prices to buyers in scarcity areas, forced to import from a distance, would have led to complaints; and the authorities would, or could, have found that this price structure, and division of the field, could not be maintained without collusive action, the individual incentive to absorb freight being so strong. The moral is uncertain, but not wholly reassuring to those who are relying on uniform mill pricing as the one legally safe course. It merely ranks, along with deliberate diversity of pricing practice, as the most nearly safe course.

Freight Absorption: Mr. Edwards's Interpretation of the Effect of the Cement Decision

It seems that Mr. Edwards reflects more accurately than Professor Fetter the present state of the law, including its ambiguity and uncertainty. He sees, as still permissible, some undefined scope for freight absorption, much reduced and not "systematic" but capable of covering a "considerable number of instances," and not limited to "isolated and sporadic transactions" (despite the language of the cement decision). At the same time he admits that, for industries that have been following basing point pricing, any practice that would produce a similar result—as extensive freight absorption would do—is "hazardous," even if done without collusion. Yet Mr. Edwards states: "There is nothing but business policy to require these sellers—both those who are under orders by the Commission and those who are respondents in cases not yet decided—to adhere to a rigid f.o.b. mill pricing system." Is this a criticism or a warning? He is inviting the companies to incur admitted legal hazards to test the meaning of the law in what is likely to prove the expensive way, by absorbing freight until the Commission "cracks

down." Elsewhere, he has indicated that a producer is safer if he sometimes beats the other price, instead of meeting it, thus forfeiting the good-faith defense in the not-too-certain hope of meeting the Commission's alternative test, of not impairing competition.⁹

The discussion contains suggestions of two different, and to some extent incompatible, limitations on price-meeting (or matching). One results from the irregularity and uncertainty incident to abolishing freight-rate conversion books, and letting customers use their own truck and water transport.¹⁰ The other would result from limiting freight absorption to cases in which the seller has collected and preserved evidence verifying the price he is meeting, to meet the burden of proof under Section 2 (b). This would be practicable chiefly in cases where rail freight is used. In the other cases there would often be no knowable price to which the concession could be equated, so the good-faith defense would not be available. But that has nothing to do with whether they are cases in which freight absorption would be monopolistic; in fact, they include precisely the kinds of cases in which the Commission has been hoping to jar loose more active price competition by introducing irregularity or uncertainty as to what the competitor has to meet, and so making oligopoly less "perfect." The discriminator would have to trust that the Commission would hold that this kind of discrimination does not lessen or injure competition.

Another suggestion, growing out of Mr. Edwards' remarks on the present situation, is that freight absorption is permissible when it is a favor to a buyer who cannot get supplies from a nearby mill. That is, it is justified in cases in which the seller has no normal economic incentive to make the concession, because he can get the business without doing so. The suggestion that this situation might be met by sellers exchanging customers is rational, but collusive, hence would be done at the peril of antitrust action.

Another implication derivable from arguments used in the cases is that freight absorption is all right if only one producer does it, but becomes wrong if his competitors do the same thing in his territory, because then the discrimination becomes "mutual," and acquires a constructively collusive character. A final rule is purely quantitative: a little freight absorption is all right; but if it becomes widespread, it will be held to be "systematic" and therefore wrong. For this reason it seems clearly unsafe for a producer to absorb freight in all the cases in which verification of the competitor's price is feasible. I submit that these do not add up to a clarification of the distinction.

⁹ In address before anti-trust section, New York Bar Association, January 26, 1949.

¹⁰ Section 2k of the Federal Trade Commission cement order seems aimed to protect diversion-in-transit, but is obscure, so long as delivered prices are permitted.

between competitive and non-competitive freight absorption: between the allowable and the legally dangerous.

Economic Effects: Lessening or Injuring Competition

In the construction of the law, the concept of "injury" to competition seems to have been used to refer to the competition between customers, while the concept of "lessening" refers to the competition between the sellers, though it is presumably an injurious lessening that is aimed at. This is a question of economics; but to discuss it rationally, it is necessary to get rid of some of the extreme or confused contentions used on both sides. On one side, is the confusion between action to maintain uniformity in methods of deriving delivered prices from base prices, and collusive fixing of base prices themselves; or the identification of "price-matching" with monopoly, by assumption. To assume—as is persistently done—that the two are identical or inseparable, forecloses the real economic question, of the effect of "systematic" freight absorption in a basing point setting, on the forces that play on the setting of base prices. On the other side, is the confusion involved in the contention that abolition of freight absorption would set up "local monopolies." This again forecloses the same real economic question of the effect on the competitive forces that play on prices; and also the same question with respect to "service." Under widespread meeting or "matching" of prices, competition in service is very active, perhaps overstimulated. Under uniform mill pricing, it would be active only at the borders of market areas, and the benefits might not spread to customers in the interiors of the market areas in the same way that price benefits would. So there is more ground for speaking of local monopolies in service than in price, as resulting from uniform mill pricing; and competition in service is not to be dismissed as necessarily unimportant. It is, of course, only part of the picture.

The real economic question may be approached *via* the much-used letter in which John Treanor stated, "that ours is an industry above all others that cannot stand free competition, that must systematically restrain competition or be ruined. . . ."¹¹ Edwards indicates the usual construction placed on this expression by using the word "avoid" in the next sentence as synonymous with "restrain." That was not Mr. Treanor's conception. The "restraint" he contemplated consisted simply of assuring such orderliness of pricing that a producer would know the price he had to meet. Lacking this, competition took on a character of piecemeal erosion, carrying prices to bankruptcy levels when capacity was excessive—as it was a large part of the time in such a fluctuating

¹¹ Edwards, *op. cit.*, p. 830.

industry as cement—and bankruptcy did not take the bankrupt capacity out of the industry, but left it as a chronic threat to standards. If he knew what he had to meet, he was willing to compete and be competed with, asking no further “restraint”; and he conceived this as fair competition.¹²

Economists will, of course, point out, correctly, that this describes a condition bringing into play the “oligopoly” principle whereby price reductions are deterred by the certainty that they will be met; and a good many of them will further hold, incorrectly, that in this case price tends in practice to a level identical with that of monopoly. This is one more instance in which neither side is unqualifiedly right. Mr. Treanor’s view was one-sided or incomplete in accepting oligopoly as equivalent to healthy competition; his opponents are one-sided in ignoring the reality of the threat of “cutthroat competition” which concerned him, and in assuming the identity of oligopoly with monopoly.

Agreements fixing prices are not the real issue; they are equally illegal under any form of pricing structure. An order to change the form of pricing structure would not prevent such agreements. But it might alter the degree of competitive pressure exerted on producers who are setting their prices without agreeing on them. And it forecloses part of the economic inquiry if one assumes at the start that any mitigation, from the most extreme degree of pressure possible, is necessarily injurious and illegal.

One might start such a comparison of different forms of pricing by assuming half a dozen or more producers, all located at the same point of origin. They will meet one another’s prices. Barring a quite limited amount of (temporarily) secret “chiseling,” any producer reducing his price will expect it to be met, down to something close to his rivals’ marginal costs (which are less than average costs) but a price increase is not sure to be met. The upshot is that the competitive incentive to reduce prices stops at something that may be called a quasi-monopoly level; but there is no dependable mechanism for raising them if they get below this level, as they might through rising costs or otherwise. So they are likely to be sticky at some indeterminate point which may be lower, but not higher, than the theoretical quasi-monopoly level. This, in turn, may approach either the competitive or the monopoly

¹² This letter, be it noted, was written under NRA, when the official theory was that competition was “injured” when it became destructively severe, and that approved codes of fair competition were exempt from anti-trust laws. The *ex post facto* disregarding of this exemption, illustrated by the use made of this letter as evidence, has backfired, as will be seen, stultifying trade-practice conference procedure.

level.¹³ One important mitigating factor arises from the widespread practice of unpublicized shading of openly quoted prices, which may be tolerated within limits, or may ultimately be regularized by a formal price reduction. This price-shading may involve discrimination, especially in favor of large and powerful customers, and therefore may incur legal danger; but if it is not too narrowly confined in this way, it may be the most active channel of price competition.

This may be taken as the type of the oligopoly situation pertinent to this class of industries. It is sheltered from tendencies to cutthroat competition by the foreknowledge that price reductions will be met, and this shelter is not guaranteed to stop at an economically correct price; but it is less powerful than monopoly, and has nothing inherently illegal about it. Now suppose these producers to be spatially separated, each with a base price which he is free to raise or lower, and each free to absorb freight. This creates another variant of the oligopoly situation. Is it closer to monopoly, or farther from it, than the first? The answer seems to be that it is closer in some respects and farther away in others. It is closer in that, if one producer raises his base price, the resulting increased delivered prices will be met by most of the competitors making freight-absorbing sales in the area where his base controls the delivered price. (They will be met, except for price-shading or "chiselling".) It is probably closer in that the producer whose preferred price is the lowest is not in a position to set a ceiling on the base prices of his competitors; each is more nearly free to follow his own bent in this respect. But the situation is farther from monopoly in that a reduced base price may discourage some of the more distant competitors from selling in those parts of the first mill's selling area where heavy freight absorption would be required.

In theoretical terms, this represents an individual demand schedule flatter than the general industry schedule, but still with considerable

¹³ For this purpose the "quasi-monopoly" level could most pertinently be defined as the maximum profit level as seen by and for one producer who expects to keep about his existing share of total sales in the industry. This would differ from producer to producer, according to their costs, and more particularly according to the long-run or short-run perspective in which they view the effect of price on sales for the industry, and on the likelihood of attracting new capacity into the industry, and thus reducing the "shares" (no agreement on quotas implied) of the existing producers. The longer the perspective envisioned, the closer the result comes to the price of theoretical competition. Also, one producer may hope to gain "good-will," or a large long-term contract by initiating a reduction, even if met. The price for the group will be determined by the producer whose circumstances and perspective lead him to set the lowest "quasi-monopoly price." He will veto an increase above this level by refusing to follow it. Even below this, an increase initiated by one producer may not be followed by the others. The rationale of meeting an increase may be a case to which the Neumann-Morgenstern chess-game method of analysis is pertinent.

slope (slope defined as ratio of change in one producer's base price to change in his physical volume of sales—both measured percentage-wise—other producers' base prices being unchanged). But in this kind of case, a horizontal or near-horizontal individual demand curve brings about the oligopoly effect, because producers know, or soon find out, that a price reduction will be met. A rational economic objective could be theoretically defined as an individual demand curve with a slope such that the price yielding maximum profit above short-run marginal cost would be approximately sufficient to cover total cost, on the average of fluctuations.¹⁴

There is bound to be a zone of uncertainty and resulting indeterminateness, and *this zone is essential to avoiding a dilemma inherent in this situation*. Without it, if price were above the equilibrium-level, there is no dependable incentive to reduce it, since a reduction is sure to be met. In a theoretical model of this sort, active price competition can go on when price is between the upper limit, where a reduction is sure to be met, and the lower limit where a reduction would be unprofitable, even if not met. The economically desirable range of slopes of the individual demand curves of the different producers is one such that the zone of uncertainty whether a price reduction be met, will extend up as far as prices are likely to go, and down as far as the desirable competitive level of price; because it is within this zone that competition acts effectively to reduce prices. This does not depend on whether the businessmen concerned analyse their actions in these theoretical terms—they obviously do not—the question is merely how they react to a rival's reduction of price. This formulation is suggested, not merely for its bearing on the basing point question, but as a general modification of the theory of oligopoly.

From this standpoint, we may look at uniform f.o.b. mill pricing to see what sort of slopes it is likely to give to individual demand curves and whether it is likely to approximate the economically desirable range. If so, it might utilize the spatial separations of the mills to bring about a more effective form of competition than would prevail if they were all at one location. That seems to be what Professor Fetter has been aiming at. A realistic answer to this question would involve an enormous amount of factual investigation, since it depends on the geographical distribution of demand. If demand is sparse in areas potentially accessible to more than one producer, the slope is

¹⁴ It is evident that the writer does not adhere to the theory that price should always be equal to short-run marginal cost. This is hardly the place to discuss that entire theory, which would require tax-subsidized deficits, and therefore is not an appropriate standard to introduce into anti-trust policy.

relatively steep. If, in such a potentially competitive area, there is a concentration of demand so great that several sellers find it necessary to secure a share of it, the decisive portion of the curve will be horizontal, each producer will know a price reduction will be met, and the oligopoly situation will result. The eastern coastal area has had this character for the potash industry, and it has been claimed that the Detroit market has the same character for some steel products, so that for these products "Detroit minus" would take the place of "Pittsburgh plus." If there are several such concentrations in debatable territory, the curves may be broken into horizontal stretches connected by sloping segments. And the curves of different producers will differ.

A simplified model, which might roughly approximate the average from which particular cases depart, could be constructed by assuming uniform distribution of demand in two-dimensional areas, disregarding possibility that price moves will be met, and making realistic assumptions as to the relation of transportation cost (or more strictly, added cost of added distance) to total cost, and of short-run marginal cost of production to total cost. Such a model, with figures pertinent to the cement industry, yields individual demand curves with slopes such that the competitive equilibrium price, while above short-run marginal cost, would be considerably below total cost.

This strongly suggests the further conclusion that, when prices are at or above total costs, producers would soon learn that any reduction would be met, and the stickiness characteristic of oligopoly would result. Then the hope of establishing more active price competition would be disappointed, possibly after a transition period of destructive price warfare during the first "buyers' market." This conclusion is supported by the fact that price-shading could not be concealed, except at points on the precise boundaries of the marketing areas of different producers; thus increasing the certainty that price reductions would be met. The chief qualification on this conclusion is the effect of changes taking place from season to season in the geographical distribution of demand, which might lead to fresh efforts to alter the boundaries of established selling areas from time to time. The effect of this seems conjectural.¹⁵ Equally conjectural is the expected stimulus to the setting-up of small independent plants, if they are deprived of the privilege of setting a high base price and absorbing freight,

¹⁵ A few of these practical considerations are listed, but not explored, in my article: "Imperfect Competition Theory and Basing-Point Problems," *Am. Econ. Rev.*, Vol. XXXIII, No. 2, (June, 1943), pp. 284, 295-96. This refers also to Smithies' "Aspects of the Basing-Point System," in this *Review*, Vol. XXXII, No. 4 (December, 1942), pp. 423-40.

in their early days. More likely is a stimulus to large companies to establish branch plants, and an advantage for existing chain mills.¹⁶

Cross-freighting of truly standardized products would be eliminated (except for cases of local shortage leading buyers to be willing to pay excess freight, as buyers are at present). As indicating the importance of this saving, Mr. Edwards suggests that the Federal Trade Commission in 1932 made an estimate of unnecessary freight for cement, and found it about 24 cents a barrel. This gives an exaggerated impression. Freight on the finished product is a larger element in final cost for cement than for steel or probably most other products, and freight absorption was substantially greater in 1932 than in years of more normal business. Furthermore, the Commission, instead of making an independent estimate of unnecessary haulage, accepted total freight absorption as a tentative indication. This cannot be assumed to be an accurate measure. The writer attempted to get a rough indication of the direction and amount by which it differs from the answer sought, by examining a considerable number of drastically simplified models illustrative of fairly typical situations, assuming mill prices that would either be based on assumed costs, or would give each producer his previous volume of sales (presumably no set of mill prices could do this precisely in practice, but there would be strong pressure in that direction). The tentative conclusion was that the available reduction of freight costs is substantially less than total freight absorption. If considerable freight absorption persists, this saving would be further reduced, as Edwards points out.

If individual demand curves (relative to base prices) are too steep under regular basing point pricing, and too flat under uniform f.o.b. mill pricing, that suggests the possibility that something intermediate might work better than either. In a simple theoretical model, the slopes could be altered as desired by allowing limited freight absorption. If Edwards is right about the results of existing rulings, the existing law would bring about an intermediate situation, but one with unpredictable effects. This intermediate character results, first, from truck and water haulage, and absence of freight-rate books, introducing greater uncertainty as to what a competitor has to meet; and second, from a reduced amount of freight absorption. As to the first, there seems to be no way of estimating its effect on competitive pressures. Industry's claim that it starts a sequence of price-nibbles, bound to end in bankruptcy, may be exaggerated; it leaves protection of the seller to his own individual good sense. As to the second, if freight absorption does materialize and is permitted, there is no way of estimat-

¹⁶ Opinions differ as to whether mere warehouses could legally be used to secure the same effect, distributing products produced in a single plant. Assembling or finishing plants would presumably be legal.

ing its probable or legally permissible amount; and the amount would be decisive in determining the effect on competitive pressures. Finally, between these two effects there is some incompatibility. The uncertainty-effect works most strongly if there is full interpenetration of selling areas. If there is none, this effect would operate only on the boundaries, and perhaps at too few points to be very effective. Strict uniform mill pricing would weaken the uncertainty-effect; it also interferes with itself, as we have seen. The result envisioned by Edwards—a moderate uncertainty-effect plus substantial, but limited, freight absorption—seems economically sound; but I see nothing in present rulings adapted to drawing lines in the economically useful places.

Conclusion: What to Do?

The Commission's victory has been so sweeping and sudden that it may not realize how great is its present power, after years of struggle and rebuff. It may not be appropriately prepared to exercise such great power, and hangovers from the period of struggle may plague it. The prosecuting arm used unsound economic theories in fighting its cases, making it hard to convince the skeptical that the Commission—not separable from its prosecuting arm—has the sound economic understanding which its present powers require. I believe it has sounder economic understanding than appeared in the concepts it used as weapons when it was throwing everything and the kitchen stove at the companies in a desperate battle to get a basis for any order that would stick. It is of incalculable importance that the quality of its real economic analysis be demonstrated. The Commission's theory of what impairs competition—which *is* the law—needs to be brought into the open. It also needs to be adapted to the new phase in which embattled absolutes may give way to a need for sensitive gauging of matters of degree. With orders in force, real economic discussion of their effect, formerly impossible, has become indispensable.

Risking dogmatism for the sake of brevity, I believe we should accept the fact that freight absorption is in a realm, the essence of which is regulation of trade practices rather than punishment for violations of specifically knowable law, and in which economic theories make the law. Regulation should remain flexible, ruling according to the essential effect rather than the specific form of practices and accepting the resulting uncertainty as to whether, for example, freight absorption is proper in a given setting. It should continue to tell business what not to do, rather than prescribe specifically what it shall do, and should seek procedures as equitable and serviceable as possible in these premises. This means shifting emphasis from collusion (real or inferred) to more realistic consideration of economic effects of practices and proposed remedies, recognizing them as matters of degree.

It may call for considerable change from past procedures.

Unless the country wants to restore unlimited freight absorption, we should go slow on substantive changes in the law. I believe it would be a mistake to introduce a statutory definition of "price," for the purpose of changing the present legal meaning of "discrimination in price." "Price" means *both mill-net and delivered price*, and both sides use it both ways, as the subject matter requires. It is the construction of the phrase, not the word, that counts; and the phrase has been construed, I believe, in accord with the intent of the original act of 1914, though the line of legality—a distinct question—has not. A statutory redefinition of "price" might protect predatory price cutting from the condemnation of Section 2. It would move litigation back to the stage in which economics is pushed aside by legalistic verbalisms—a stage from which we may hope to be rescued by the completion of the basic litigation. In that way it would be a move in the wrong direction.

There is more ground for relieving business of the burden of proof of "good faith" under Section 2 (b), and giving it the benefit of normal business judgment in meeting competitive prices. If occasionally beating a rival's price, rather than always meeting it, is included among types of approved conduct, the words "an equally low price of a competitor" should be changed to permit the approved practice. Sufficient remedies against predatory price cutting would remain.

But the principal changes should be procedural, recognizing that honest disagreement on economic theories should not convict anyone of illegal intent; and that penalties for violation of a Commission theory, not previously and clearly announced and upheld, are *ex post facto* and improper. A cease-and-desist order may amount to a penalty, heavier than a fine which would be regarded as "excessive." Such orders should follow procedures adapted to relieve their *ex post facto* character. The most logically appropriate procedure for making the law specific—the trade-practice conference—is probably useless, since there is too much likelihood that the necessary joint action could be used as evidence against the companies in later complaints, as things done and written under NRA were used. Hence the companies would not dare go beyond innocuous platitudes; and the Commission would be similarly chary for fear of impairing its future freedom to attack any practice.

I believe the most useful changes would be of the following sort. In a finding that an existing practice impairs competition, the Commission should be required to state its reasons for its finding, enunciating its theory of impairment, defined as making things worse than some alternative condition that could conceivably come about in the specific conditions of the industry in question. This should be done

in the complaint, making it arguable in the Commission proceedings as well as on appeal. This would exclude much of the economists' testimony taken in the cement case, and require testimony of a more relevant sort. As to the nature of the alternative condition, there is a dilemma: the most logical alternative is one that could come about spontaneously, but the most practically pertinent may be one that only a Commission order could bring about. I suggest that the prosecuting arm of the Commission have the option of using an alternative of the latter sort, which would then be arguable before the Commission itself, not binding the Commission, but giving it the benefit of the resulting argument in framing its final order. Findings based on this optional standard could not carry penal consequences.

Orders should be subject to a similar requirement of 'a showing of positive ground for believing that the order is adapted to improve the condition complained of. This is intended to add to the present requirement that the remedy should have some appropriate relation to the offense: a requirement suited to disciplinary action against known wrongful acts.

Such changed requirements should go into effect only after a waiting period, to allow the Commission time to develop and consider its theories, in the light of the responsibilities thus imposed. If the Commission realizes its present powers, and the responsibilities and changed equities that go with them, including the seriously demoralizing effects of its present relations to business, it should realize that changes of the general character proposed would put it in a sounder position and increase its moral authority. This would be in its own best interest.

Finally, these cases emphasize the need for availability of impartial *amicus curiae* testimony and expert advice, for both Commission and courts. If, as I believe, the Court has slipped at points into bad law in both the Staley and cement cases, it is because it had only partisan arguments to choose from. No theory of public interest was available from an impartial source; and it is too much to expect the Court, in such involved matters, to construct out of whole cloth its own fresh theory of public interest. This proposal might mean the growth of a new profession of legal-economic counsel, starting with the existing nucleus of personnel trained in both fields.

The issues are much broader than basing point problems. They concern the working-out of methods, consistent with American ideals of responsible government, for handling highly specialized and technically complex issues of regulation of trade practices. These threaten the essentials of democracy if they are not effectively regulated, and threaten them equally if regulation, to be effective, has to be freed from proper standards of accountability.

A NOTE ON PRICING IN MONOPOLY AND OLIGOPOLY

By JOE S. BAIN

The conventional versions of a *a priori price* analysis apparently suggest that a single-firm monopoly or a collusive oligopoly will choose a price-output combination such as to maximize *the industry profit*.^{*} Product differentiation and selling cost being neglected, the currently established firm or firms are supposed to equate their marginal costs to the marginal revenue drawn from the industry demand curve for the commodity which they produce in common. This balance should presumably be struck over any long period between long-run marginal cost and the marginal revenue from the long-run industry demand, and in any short period between short-run marginal cost and the marginal revenue from the short-run industry demand. Price in either period should be set to maximize the difference between the aggregate revenue from the sale of the given commodity and the aggregate cost of its production by any established group of firms. Empirical studies of price policy by monopolists or by oligopolists with *apparently* effective collusion on price, however, frequently fail to sustain these predictions. In many such industries, short-run outputs at which short-run marginal costs plainly exceed short-run industry marginal revenue are apparently common. But more striking is the evidence in some of these industries of prices held persistently over many years within a range where the industry demand curve is evidently inelastic, the corresponding marginal revenue thus being negative and necessarily below long-run marginal cost.¹ This indicates a prolonged tendency (potentially for a theoretical "long-run") to hold price well below the level which would maximize the difference between aggregate revenue from the sale of the industry's commodity and the aggregate cost of producing it,² and apparently contradicts the basic *a priori* predictions of a theory of collusive pricing.

This apparent impasse has been variously resolved by students of industry with suggestions: (a) that sellers do not try to maximize monetary profit; (b) that they err in their attempt to maximize profits;

^{*} The author is associate professor of economics at the University of California, Berkeley. He is indebted to Professors H. S. Ellis, W. Fellner, and R. A. Gordon for helpful criticism of the paper and for a number of substantive suggestions.

¹ Two fairly convincing examples of this are the cigarette and steel industries.

² Of producing it, explicitly, with the "given" number of firms, but also with any other conceivable number of firms if industry marginal revenue is negative.

(c) that in the face of great uncertainty concerning demand they simply add some markup to normal average cost and hope for the best; (d) that they fear government interference and public ill will if they exploit their monopoly positions fully; (e) that the apparently collusive oligopoly is not fully or successfully collusive, so that rivalry keeps price down; (f) that sellers set low prices for very considerable time periods in order to raise the level of future industry demand; and (g) that *established sellers* persistently or "in the long run" *forego prices high enough to maximize the industry profit* for fear of thereby attracting new entry to the industry and thus *reducing the demands for their outputs and their own profits*.

Although each of these explanations may contain an element of truth as applied to particular cases, they proceed on somewhat different levels in their implied criticisms of conventional theory. The rejection of profit-maximization as a goal suggests a corresponding rejection of conventional price theory; the thesis that either errors or uncertainties are dominant suggests that if such theory is basically valid in its assumptions it nevertheless has little genuine value for predicting actual price results. The suggestion that oligopolistic rivalry reduces prices below the monopoly level leaves theory unscathed, simply implying that the model for monopoly pricing has been misapplied. On the other hand, the hypotheses concerning fear of interference, threat of entry, and pricing to stimulate future demand do not deny that the observed results may be explicable in terms of a theory of monopoly or collusive oligopoly price which assumes profit maximization, effective collusion, and approximately given data, but suggest that the industry or seller demand curves employed in that theory must be redrawn to reflect explicitly the effects of the phenomena in question.

Until the results of such a redrafting are explored, we cannot properly assess the potential explanatory value of conventional price theory. In this paper, we examine two possible modifications of the theory of monopoly price, to take account first of the relation of present price to future profit and second of the impact of the threat of entry;³ in the latter case we suggest certain possibly novel conclusions concerning the unit for which profit may be maximized and the relation of marginal cost to marginal revenue.

Interperiod Demand Relationships

An elaboration of conventional theory to recognize the relation of current price to future demand has been suggested by M. W. Reder;

³ Although the threat of government interference will not be treated explicitly, it could be handled in about the same manner as entry.

it may deserve re-emphasis in connection with the present issue.⁴

The monopolistic firm (or group of collusive oligopolists⁵) may be provisionally viewed as dealing with an entire industry demand curve in a succession of time intervals, in each of which it can freely select a price-output combination for the industry. It will thus logically take account of the effect of any current price-output decision on the position of the industry demand curve in future periods. A lower price now may mean a larger (or smaller) demand later, and any such anticipated relationship should affect any current pricing policy. If it does, a single long-run industry demand curve cannot be viewed as an independent determinant even of the long-run tendency of price. Such a relation is then not given independently of the prices which the seller(s) charge at various times during the future, but will assume various levels according to the behavior of a series of short-run prices. Instead the seller(s) necessarily refer to a series of short-period demand curves for each of a succession of future intervals; these fully replace any long-run demand curve for the purposes of making all output adjustments. And we must now speak not of a single long-run tendency for price, but rather of a price-pattern through time.

A simple model can be constructed in which a single-firm monopolist is conceived of as pricing solely in a current Period I and a future Period II. There is an industry demand curve for each such period and a corresponding pair of marginal revenue curves. Monopoly price for the first period in isolation would be set to equate the marginal cost of that period to the marginal revenue of that period. But demand in Period II may be supposed to depend upon Period I price; for example, the Period II demand curve may shift outward as Period I price falls. Viewing this relation in prospect from the beginning of the first period, the monopolist may be supposed to adjust Period I price so as to allow maximization of the sum of the profits of the two periods. This procedure may result in setting Period I price below the level for which the marginal cost and marginal revenue of that period are equated, so long as the resulting decrement to Period I profits is more than offset by a resulting increment in Period II profits (as appropriately discounted for interest and risk).

Use of the demand-supply technique in such a sequence analysis permits precise formal treatment of the effects of anticipated relations between current price and future demand. To employ the analysis

⁴ "Intertemporal Relations of Demand and Supply within the Firm," *Canadian Jour. Econ. and Pol. Sci.* (Feb. 1941), pp. 25-38, and especially pp. 32-35.

⁵ For a simplified argument, we will suppose the collusive oligopoly in each case to be a "pure" oligopoly, in which the several firms sell identical products at a necessarily identical price (the possibility of discrimination being neglected).

for purposes of prediction, we should attempt to determine the sign and value of the cross-elasticity between Period I price and Period II quantity for the monopolist—

$$\frac{\partial q_{(t=2)}}{\partial p_{(t=1)}} \cdot \frac{p_{(t=1)}}{q_{(t=2)}}$$

One can identify actual cases where this elasticity might be alternatively positive or negative in sign, or zero. Where it is negative and significantly large, a current monopoly price below the current profit-maximizing level can be formally explained; where it is positive and large, current prices above this level could be predicted. This model of course does not have the monopoly doing other than to maximize the "long-run" difference between aggregate industry revenue and aggregate production cost, so long as these are measured as capital values of future revenue and cost streams to a time horizon. But it does indicate the rational possibility of deliberate departures from profit maximization for "short" periods longer than those required to permit every adaptation in scale of firm and plant.

The Threat of Entry—General Considerations

Let us now turn to the effects of anticipated entry. Even a single-firm monopoly is not necessarily impregnable to entry if the industry is a very profitable one, and in oligopolistic industries the threat of entry is likely to be stronger. The monopolist or the group of collusive oligopolists might therefore be viewed as setting each of an indefinite succession of current prices or profits with an eye to their effect in attracting entry into the industry and thus in reducing the demand for the output of the now-established firm(s).⁶ One possibility is that the initially established seller or collusive sellers will be faced with the choice of (a) setting each of a succession of short-run prices (and hence long-run average price) so as to maximize the *industry* profit, but with the result that added firms enter the industry and reduce the share of industry profit gained by the initially established firms, and (b) setting each short-run price (and hence long-run average prices) at a lower level, thus discouraging further entry, and keeping the smaller (and non-maximized) industry profit all for themselves. Should the second course then offer larger long-run profits *to the initially established firms*, they would presumably follow it, and price could for the indefinitely long run lie below the level required to maximize the difference between the aggregate revenue from the sale of the given commodity and the ag-

⁶ The threat of entry, and its relation to price, will of course depend upon the height and effectiveness of such institutional barriers as patent holdings, control of raw materials, etc.

gregate cost of producing it. Long-run maximization of *industry profit* and of *the profit of a group of currently established firms* may not coincide. This is presumably a thesis implied by those who point to threat of entry as a factor holding price below the level which would maximize the long-run profits of the industry.

This hypothesis can easily be developed on a formal level if we accept two premises upon which it must implicitly be based. These are (1) that the established monopolist or group of collusive oligopolists are aware of any real threat of entry to their industry, and will adjust to it in such a way as to enhance their own (as distinguished from industry) profits, and (2) that potential entrants to such a monopoly or oligopoly are primarily influenced in deciding whether or not to enter by the prices charged and profits currently earned by the established firms. The first premise seems only reasonable,⁷ but the merit of the second could be contested. A potential entrant to a purely competitive industry is presumably guided entirely by the expected long-run tendency of industry price as related to his contemplated costs. This is because his increment to the industry would neither perceptibly influence the price nor engender any direct reaction from any established seller. The potential entrant to a monopoly or oligopoly, on the other hand, who will typically make a substantial lump increment to the industry capacity (since economies of scale will ordinarily require a fairly large firm), may expect both to influence the pre-existing price and to elicit some reaction from the established seller(s). This holds whether or not he contemplates collusion with those sellers. In effect, there is a special sort of oligopolistic interdependence between the established seller(s) and the potential entrants in such instances, and it is not entirely plausible that the potential entrant should entirely neglect this interdependence and view the going industry price as the principal indicator of whether or not entry will be profitable.

At the extreme, it could even be argued that a potential entrant to an oligopoly should pay little regard to price or profit received by established firms, especially if he thought price was being held down in order to "bluff" him away from the industry. He should look at the industry demand, the current competitive or collusive conditions in the industry, the prospects for rivalry or collusion after his entry, the share of the market he expects to capture, and his projected costs of production. Paramount in his considerations, provided the industry demand under some conceivable arrangement could provide profits to an entrant, should be his appraisal of the sort of rivalry and the type of price policies he will encounter from the previously established seller(s) after

⁷ To argue that sellers in concentrated industries deliberately disregard the consequences of threatened entry would picture them as unbelievably stupid.

he enters. In judging these determinants of his decision, current price or profit in the industry need play no *direct* role, since the anticipated industry price *after entry* and the entrant's anticipated market share are the strategic considerations. And if he knows the industry demand with reasonable certainty and makes calculations concerning the conditions of rivalry after his entry, upon which he is willing to act, he might look entirely past any current price set by the established firm(s). He then would be immune to bluffing, and the established firm(s) could never discourage entry by lowering prices and earning moderate profits.

The supposition that the potential entrant's judgment of industry demand and of the rivalry he will meet is entirely unrelated to current price or profit in the industry, however, probably goes too far. Even if he does not believe the observed price will remain there for him to exploit, he may nevertheless regard this price as an indicator both of the character of industry demand and of the probable character of rival policy after his entry. Industry demands are never certainly known, and they are probably known less fully by potential entrants than by established firms. The fact that the established firm(s) make only moderate profits may thus create in the mind of the potential entrant sufficient uncertainty concerning the elasticity of the industry demand curve at higher prices to deter him from entering. Moreover, he may view the price which the established firm(s) currently charge as a partial indicator of the rival price policy he will face after entry. Other considerations should influence his judgment of projected rivalry, but current pricing may be a critical factor in evaluating it. It is thus possible that the potential entrant is influenced by current prices and profits and that there may be a critical price below which he will not enter and above which he will enter. This hypothesis seems plausible enough so long as the potential entrant regards the current pricing policy of established sellers as being probably a statement of intentions rather than a bluff. It is probably more plausible than otherwise when applied to oligopolies where product differentiation is not very great, and where the entry problem is thus not unduly complicated by the necessity of gaining buyer acceptance of a new product. We will speak here primarily of its application to oligopolies with relatively slight product differentiation.⁸

On the basis of the preceding argument, we may provisionally accept the second premise of the thesis concerning threat of entry, that the potential entrant to a monopoly or oligopoly is primarily influenced by

⁸ It may be added that with imperfect market information, "potential entrants" may be made aware of the possibilities of an industry mainly by its profit record, and will never present an active threat if they are not alerted by high profits. In this case, low current prices and profits may serve as a deterrent to entry because they do not attract attention and thereby create actively potential entrants.

the price charged (and profit earned) by the established seller(s)—influenced not because he expects this price to hold unchanged after entry, but because he regards it as “proving” the industry demand at a given level and as a critical indicator of the projected state of rivalry or price policy after entry. Accepting the first and second premises, we may now investigate their formal implications for the price policy of an established monopolist or group of collusive (pure) oligopolists faced with a threat of entry. What will happen in these cases if (a) the established sellers(s) anticipate any threat of entry (highly probable), (b) potential entrants are influenced in their entry decisions by current price in the industry (a strong possibility), and (c) the established seller(s) know this and consider adjusting their prices to discourage entry.

A “Limit Price” Analysis

For a formal treatment, two special concepts may be conveniently employed. The first is the “limit price,” or highest common price which the established seller(s) believe they can charge without inducing at least one increment to entry—presumably a significant lump increment. This limit price depends ultimately upon the cost functions which potential entrants expect to have, upon their estimates of the industry demand and of the share of the market which they can capture if they enter, and upon their view of the degree of competition or collusion which will obtain in the industry after their entry. The subjective estimate of this limit price by the established seller(s), however, rather than the view of potential entrants, is the real determinant of the price policies of the established seller(s). Since the limit price must be defined in terms of the guess of the established firm(s) concerning the anticipations of the potential rivals, it is especially subject to error as an *ex ante* magnitude, and it may be invalid if potential entrants read it as a bluff. But it is nevertheless potentially valid and determinate.⁹ The second concept is the estimate by the established seller(s) of the conditions of demand for their outputs after entry occurs in response to their setting a price above the limit. This involves their estimate of the market share they will lose to an entrant, and also of the conditions of competition or collusion which will obtain after entry. If the established seller(s) formulate estimates on limit price, as defined, and on the position and character of the demand for their outputs after entry, these estimates can be recognized in an anticipated demand curve or sequence of demand curves for their outputs, and a formal solution developed.

This solution can follow the lines developed for the case of inter-

⁹ Account must be taken, of course, of the consequences of erroneous as well as correct estimates of this price by the established seller(s).

dependence of prices through time. We can first construct a given industry demand curve for the current Period I and for Periods II, III, etc.¹⁰ The demand for the output of the established seller(s) in the current Period I is the industry demand of that period. In any later period, however, it can be expected to be the same as the *industry* demand only so long as price in the preceding period has remained at or below a limit price, A, so that entry has been forestalled. If any given period price is set above A, the demand for the output of the established seller(s) in all later periods is expected to become less than the industry demand by the amount of a market share going to the new entrant, and it may be otherwise altered or made uncertain if effective collusion with the entrant is not contemplated or considered attainable. If entry will occur in discrete lumps, moreover, the demand for the output of the established seller(s) in later periods does not shift continuously in response to variations in Period I price. Instead it makes a discrete shift backward if A is surpassed in Period I, and the solution is affected by this discontinuity. Given these conditions, the established seller(s) will devise a price policy for Period I and in all later periods so as to maximize the discounted present value of profits for all future periods. With an effective threat of entry, it is potentially consistent with such profit maximization by the established seller(s) that price will be held at the limit level continually through time, even though this limit price may in every current period be lower than that for which the marginal cost of the established seller (or horizontally added marginal costs of the established sellers) equals the marginal revenue drawn from the industry demand curve for that period. Such a solution can be determinate and give stability without entry for the indefinitely long run (permitting all desired adjustments of scale by the existing firms) provided the limit price estimated by the established seller(s) is in fact low enough to exclude entry. If the established seller(s) set a "limit" price which turns out to be too high to exclude entry, of course, their error may result in an effectively irreversible change in the structure of the industry.

Because the sequence analysis is unnecessarily awkward for dealing with the threat of entry, the preceding solution is only sketched. Assuming no interdependence of the *industry* demands of successive time periods to be involved in the case, the impact of a threat of entry can be analyzed more easily by referring to the anticipated long-run demand conditions for the output of the established monopolist or collusive oligopolists—or to the expected response of their long-run average sales to changes in the average level of price they maintain

¹⁰ Each such industry demand curve is assumed to be independently given in the absence of inter-period price relationships.

over long periods. Following this course, two alternative models may be developed, one assuming that the established seller(s) anticipate rivalry and lack of agreement with any new entrant, and the other assuming that they anticipate collusion with any new entrant.

The first model postulates (1) a determinate long-run demand curve for industry output, which is unaffected by price adjustments or by entry; (2) occupation of the industry initially by a single-firm monop-

FIGURE 1

list or group of effectively collusive pure oligopolists; (3) estimation by the established seller(s) of a limit price above which a "lump" of entry will be attracted; and (4) considerable uncertainty on the part of the established seller(s) concerning the conditions of demand for their outputs if entry is attracted. Given these conditions, the anticipated long-run demand for the output of the established seller(s) may be analyzed as follows. The long-run industry demand curve is supposed to be the line $DABD'$, as in Figure 1, and the marginal revenue drawn

to it is Dabm. This demand is assumed to be unaffected by any adjustments sellers may make. Suppose now that the limit price above which the established seller(s) expect an increment of entry is Q_aA : If they charge more than this (or produce less output than OQ_a , thus causing the effective market price to exceed the limit), they expect to experience some indeterminate loss in sales volume to an entrant and some indeterminate change in price. The anticipated demand curve for the output of the established seller(s) above the price Q_aA thus is *not* DA. They have the truncated demand curve AD' to exploit up to the price Q_aA , and the corresponding marginal revenue segment am . But if they raise or attempt to raise long-run price above Q_aA , the anticipated long-run demand curve for their output becomes indeterminate somewhere in the range to the left of A. They thus have the choice of the truncated industry demand curve AD' for exclusive exploitation up to the price Q_aA , and an indeterminate demand for their outputs if they once go above Q_aA . It should be especially noted that they are unable to sell less than the amount OQ_a at the price Q_aA and thus to exclude entry, since this would result in an effective market price higher than the limit, *via* resales, and thus presumably "reveal the bluff" and attract entry.¹¹

The alternatives open to the established seller(s) are now (1) to sell more than OQ_a at a price below Q_aA , thus excluding entry, (2) to sell OQ_a at the price Q_aA , also excluding entry, and (3) to raise price above Q_aA , or reduce output below OQ_a , thus attracting entry and taking chances on profits and prices in the ensuing indeterminate situation. They will presumably pursue the course that promises to be most profitable, taking account of the fact that profits under courses (1) and (2) are relatively determinate whereas profits under course (3) are indeterminate and hence highly uncertain. The established seller(s) will follow the first or second course in preference to the third wherever the relatively certain profits offered by those courses exceed the heavily risk-discounted gain attainable if entry is attracted *via* higher prices. The possible positions in which the established seller(s) in various industries may find equilibrium may be illustrated as follows. Suppose a single long-run marginal cost curve, for the initially established monopolist, or alternatively a uniquely determined aggregation of marginal cost curves for the initially established collusive oligopolists in any industry. This we label MC. Now first this marginal cost may in some industries lie at MC_1 (Figure 1), intersecting the relevant industry

¹¹ We exclude herewith the possibility of effective private rationing or price discrimination by the established seller(s), which might enable them to produce less than OQ_a and still hold the effective market price at Q_aA ; this appears to be a special and unlikely case.

marginal revenue segment am .¹² Then the established seller(s) will almost certainly set price and output by this intersection, provided average costs are less than the resulting price. In this case, industry profit will be maximized at a price below the limit, entry will be forestalled, and the number of sellers in the industry will be in long-run equilibrium. Conventional monopoly maximization is possible without further entry being attracted. This case subsumes all those where entry is blockaded or where the limit price is so high as to be economically irrelevant.

Second, marginal cost may in other industries fall at MC_2 , lying above industry marginal revenue but below price at the limit output OQ_a , with average costs less than Q_aA . In this case, provided the profit offered seems preferable to the gamble of inducing entry, the established seller(s) will produce OQ_a and sell at Q_aA . (They will then not choose the intersection of MC_2 and the marginal revenue D_a , since this would give a price which would induce entry.) In this case entry is also forestalled and the number of sellers in the industry is in long-run equilibrium, but marginal cost exceeds industry marginal revenue and *industry* profits are not maximized.

Third, marginal cost may fall at MC_3 , lying above price at the limit output OQ_a , but with the corresponding average cost lying below price at this output. The established sellers will still choose to produce OQ_a and sell at Q_aA , so long as the resulting profit is considered preferable to the gamble if entry is induced. Again the number of sellers will remain constant, but industry profits will not be maximized and *marginal cost will exceed price*—not a probable but nevertheless a quite possible and rational result.

The general argument developed for the last two cases may also be applied on the supposition that the limit price lies at some level Q_bB on the industry demand curve, where this demand is less elastic than unity and the relevant marginal revenue segment, bm , is entirely in the negative range. We may still have equilibrium with entry forestalled at the limit price Q_bB (not rationally below it) with marginal cost above industry marginal revenue and possibly above price, but with the difference that industry marginal revenue is negative.

These solutions involve the premises that potential entrants recognize a limit price below which they will not enter, and that the established seller(s) know this and do not overestimate the limit price. Should

¹² In this and each of the succeeding cases we refer to distinct industry situations, each with a separate limit price, a separate initial marginal and average cost function, and a different relation of marginal and average cost to the limit price. We do not suggest different relations of cost to limit price in a single industry, but rather differences among industries in this respect.

potential entrants fail to be influenced by price, a stable solution will not result if entry promises to be profitable; if they are so influenced but the established seller(s) set too high a price, there will be entry and a probably irreversible change in industry structure will result. One qualification may be added to the preceding argument. In deciding whether or not to go above the limit price, the established sellers should count in favor of the former course any transitional extra profit they may earn after going above the limit and before entry becomes effective.¹³ This consideration has not been formally treated in the preceding model.

A fourth possibility is that average cost for the established seller(s) will lie above the limit price Q_aA at the output OQ_a , marginal cost lying above or below price. In this event price will presumably be set above the limit and entry attracted, provided there is some possibility of making profits at smaller outputs.¹⁴ The number of sellers in the industry then could not be stable until further entry had occurred.

Considering the various possibilities, there is a very good *a priori* chance on the assumptions drawn for the threat of entry to force a significant departure from what have been viewed as the conventional long-run monopoly-equilibrium price and output in single-firm monopoly or collusive oligopoly industries. It has been conventionally supposed that the single-firm monopolist will set a price such as to maximize long-run *industry* profit, and that collusive oligopolists will do likewise. It has been further suggested that this may result, at least in collusive oligopoly, in the attraction of entry to the point where excess profits are small or absent and the industry contains an excessive number of firms.¹⁵ But under the assumptions of anticipated entry and a response of entry to price, we see that, consistent with profit maximization *by firms*, the price in such industries may be lower and the output larger than would maximize long-run *industry profit*. A vigorous threat of entry which at an appropriate time is anticipated and forestalled, moreover, may serve to keep firms producing at outputs which give a fairly close approximation to optimum average costs. If the firms in an industry are so few that they would encounter serious diseconomies of scale in supplying the limit output, they may be unable profitably to forestall entry. But when the number of firms becomes such as

¹³ In a dynamic model, we might consider the possibility of a critical or maximum short period during which established sellers could temporarily go above limit price without attracting entry, returning price to the limit in time to discourage potential entrants.

¹⁴ In this case, however, the potential entrants presumably being able to attain lower average costs than established firms, it is doubtful that any price stratagem would forestall entry.

¹⁵ E. G. Chamberlin, *The Theory of Monopolistic Competition*, 1st ed., pp. 100-108.

to allow production of the limit output at near-optimum average costs, excessive entry may be profitably forestalled by limit-pricing policies and an economical adjustment of capacity to demand perpetuated.¹⁶

The preceding hypotheses are developed on the basis of certain crucial assumptions, of which the only really controversial one is that potential entrants to concentrated industries may be significantly influenced in their entry decisions by the prices set by established

FIGURE 2

sellers. This assumption may or may not find extensive empirical support. But the observed price policies in a considerable number of oligopolistic industries with apparently effective collusion on price are consistent with hypotheses developed from the assumption, and we may have a thesis of real explanatory value.

The model discussed above also rests on the assumption that the established seller(s) are uncertain of the rivalry which will exist if

¹⁶ It is of course evident that if once an oligopolistic industry gets an excess number of firms—whether because the threat of entry is overlooked, or because the limit price fails to forestall entry, or because industry demand declines—then there is no evident force which will eliminate firms and give such a good adjustment. But it nevertheless holds that excessive entry *may* be deliberately forestalled in the manner described.

new firms enter the industry. Its conclusions are not essentially modified, however, if we assume instead that the established seller or collusive sellers contemplate effective collusion with any new entrants. If this is assumed, together with the assumption of a determinate industry demand curve and an anticipated lump of entry above a given limit price, the analysis develops as follows. The long-run industry demand curve is DAD' (Figure 2) and the marginal revenue drawn thereto is Dam , as before. Similarly the limit price is Q_aA ; above it the demand for the output of the established seller(s) is not DA , and the marginal revenue segment Da cannot be exploited by the established seller(s). If the established seller(s) go above the price Q_aA or below the output OQ_a , however, the resultant entry does not render the demand for their outputs indeterminate, since effective collusion with any entrant is contemplated. Presuming that the market share going to the entrant under such collusion is calculated, the established seller(s) anticipate a determinate loss of the total market volume to the entrant at each possible price. Then if they raise or attempt to raise long-run price above the limit, the anticipated long-run demand for their output becomes some determinate curve DD'' , lying to the left of the industry demand curve by distances representing the share of the industry output an entrant would obtain at various prices. The corresponding marginal revenue is Dm' .

As an approximation we may say that the established sellers' demand function is discontinuous horizontally, made up of the segment AD' below the price Q_aA and the segment $A'D$ above that price. This is not precisely accurate, however, since the attempt by established sellers to charge more than Q_aA , involving attraction of new entry, might result in a collusive equilibrium price *after entry* which lay below Q_aA . The curve DD'' thus can have a meaningful price range which overlaps that of AD' . The diagram may therefore be read as follows: the established sellers can in the long run sell any of the price-output combinations on the line AD' (the quantities OQ_a or larger) without attracting entry. If they go above the price Q_aA , or attempt to, they thereafter in the long run can sell any of the combinations on the line DD'' , with the remainder of the industry demand going to a new entrant or entrants. In effect, the established seller(s) are given the choice between the truncated industry demand curve AD' for exclusive exploitation and the non-truncated share of the industry demand curve, DD'' , for exploitation *via* collusive agreement with the new entrant.¹⁷ The AD' and DD'' curves adequately compare the revenue alternatives of the established seller(s) with

¹⁷ The latter curve might also be truncated at a higher level due to an additional threat of entry, but we will focus attention here on a single increment of entry.

and without entry, so long as we neglect any transitional extra profit which the established seller(s) might enjoy while raising above Q_aA but before entry became effective. If such a transitional profit is significant, it must be considered as augmenting that long-run average profit which is obtainable by exploiting DD'' after entry.

If we place the long-run marginal cost of the established seller(s), as previously defined, against this demand complex, conclusions generally consistent with those already developed emerge. Suppose that the marginal cost of the established seller(s) lies at MC_1 , so as to intersect industry marginal revenue in the range am , where price can be below Q_aA . Provided that total profit at the output OQ_1 , determined by the intersection of MC_1 and am , is positive and exceeds profit at the intersection of MC_1 and Dm' , the established seller(s) will produce OQ_1 , charge a corresponding monopoly price below Q_aA , and maximize industry profits without attracting further entry.

Suppose instead that the marginal cost lies at MC_2 , so as to lie above industry marginal revenue at the limit output and to intersect the marginal-revenue-after entry, Dm' , at an output, OQ_2 , which gives a price above Q_aA (average cost being less than Q_aA at OQ_a). The established firm(s) can supply the entire industry demand OQ_a at the price Q_aA , or part of the industry demand, OQ_2 , at a higher price. They will choose between these discrete alternatives by comparing *the lump increment to total revenue* with *the lump increment to total cost* which are incurred in moving from OQ_2 to OQ_a .¹⁸ If the revenue increment exceeds the cost increment (the area under MC_2 between Q_2 and Q_a), they will produce at OQ_a , sell at Q_aA , and exclude entry. The profits of the industry will not be maximized, but those of the established seller(s) will be. This holds for MC_2 in successively higher positions until the cost increment exceeds the revenue increment between Q_2 and Q_a ; even production at OQ_a with marginal cost above price is possible. When the lump cost increment exceeds the lump revenue increment, price will be raised above Q_aA and entry will be attracted. (Average cost must of course always be covered at the best output or exit from the industry will occur in the long run.)¹⁹

¹⁸ This lump increment to revenue if the limit output is chosen (as aggregated over all future periods) must be considered as reduced by any transitional extra profit receivable after raising price above the limit but before entry becomes effective.

¹⁹ The general conclusions also hold if the marginal cost lies so as to intersect Dm' where price would be below Q_aA , and to lie above industry marginal revenue at OQ_a . The limit output will be produced and entry excluded so long as the revenue increment exceeds the cost increment between the alternative outputs. In this case we have the situation that collusive price after entry would lie below the limit price which should presumably attract entry. If we remember that the limit price is not necessarily the minimum which entrants expect after entry, however, this situation is not necessarily anomalous.

On the supposition of collusion after entry, we thus arrive at conclusions regarding price similar to those developed when assuming uncertain rivalry after entry. It may be objected, of course, that if established sellers assume collusion after entry, and potential entrants assume it too, then these potential entrants should not be much influenced by the current prices of established sellers, and that a limit-price analysis is thus implausible. It becomes plausible evidently only if potential entrants are quite uncertain about industry demand and about how they will be welcomed by established sellers. But such an incongruity of attitudes is itself not implausible, and the model just developed may thus constitute a realistic variant of our first model.

In summary, a considerable elaboration of the theory of monopoly and collusive oligopoly price may be implied if we assume that potential entrants to an industry are influenced by the going prices therein, and that established sellers anticipate and, if it is profitable, forestall entry. Assuming correct appraisal of limit prices by established sellers, we get three major possibilities: (1) pricing to maximize industry profit with no entry resulting; (2) pricing to forestall entry with industry profit not maximized but the profit of established sellers maximized; and (3) pricing to maximize industry profit but with resulting attraction of additional entry. The first two cases find industries already in long-run equilibrium; the third finds industries in process of dynamic change in structure.

Extensions and Applications of the "Limit-Price" Analysis

The limit-price models just developed, tracing the effects of a sort of oligopolistic interdependence between firms already in a concentrated industry and potential entrant firms, are essentially variations on the general theory of oligopoly price. There is an apparent similarity of the construction to the familiar kinked demand curve analysis, but in the present case the average revenue as well as the marginal revenue is discontinuous, and it is a revenue function for all firms already in an industry rather than that for a single oligopolist which is so affected. The limit-price analysis applies to collusive oligopoly behavior, whereas the kinked demand curve model refers explicitly to the action of a firm in non-collusive oligopoly. And the essential conclusions of the two models are of course different.

Various extensions of "limit-price" reasoning suggest themselves. Thus some firms established within an oligopoly may hold price down for fear of "fattening" their smaller rivals sufficiently to encourage their expansion. Departing from the realm of pure oligopoly, established collusive firms might extend selling costs beyond the point of industry profit maximization in order to discourage entry, so that

the threat of entry could cause increased costs rather than reduced prices. The model developed above could also be elaborated to take explicit account of dynamic changes, of varying time lags involved in the "gestation" of new entry, *etc.* Any extensions along these lines might contribute to a more realistic theory of oligopoly price.

The explanatory value of the limit-price hypotheses of course remains to be determined. On *a priori* grounds they appear to be fruitful, although alternative explanations of observed "low-price" policies may also be valid. Some systematic empirical check of the extent of "limit price" thinking within concentrated industries, and especially by price leaders, would seem desirable. Direct verification of the crucial hypotheses from *ex post* statistical results, however, would be difficult. The "limit price" in any industry, even if recognized, must change over time in response to variations in industry demand, in factor prices, in the availability of capital to potential entrants, in the age of the industry, and so forth. The single limit price of our static long-run analysis becomes in fact a dynamic variable, and would have to be treated as such. It would be difficult to establish in a strictly objective fashion, and knowledge of its recognition by sellers or of its magnitude might best be gained through interview techniques. It would be somewhat easier, on the other hand, to check observed price results for consistency with the hypothesis, without relying on the subjective impressions of sellers involved. That is, objective calculations of the probable limit price (or time series of limit prices) could be made for any industry, and the prices actually charged in a supposedly collusive oligopoly could then be compared both with such limit prices and with prices calculated to maximize industry profits. Wherever behavior consistent with the hypothesis was found, direct investigation of policies of price calculation might be indicated. The emphasis often placed on non-profit motives, uncertainty, irrationality, and oligopolistic rivalry as explanations of low-price policy in concentrated industries may be unduly heavy, and the effects of threatened entry seem certainly to deserve consideration.

THE STATE OF THE "NEW ECONOMICS"

By HOWARD S. ELLIS*

The general conclusions to be drawn from a newly published volume of essays on *The New Economics*¹ seem to be that Keynes has influenced economic theory and policy as has no one else, living or dead; that much of his influence is beneficial; but that much, if indeed not most, of the theoretical innovations of the *General Theory* are acceptable only with extensive reservation or unacceptable as descriptions of reality. The subtitle of the volume to be reviewed correctly stresses Keynes' *influence*, and the main title the novelty of his positions. The only misleading feature may be the juxtaposition of the subtitle with the phrase "*the new economics*." For it is amply evident, if one compares certain appraisals of the *General Theory*, written ten or twelve years ago and reproduced here, with the essays written for the present collection,² that the former proclaimed the new doctrines confidently and without qualification, but that the latter—as we shall see—generally present more qualification and addition than original substance. How much Keynes contributed in his last major book depends on whether one stresses the *impulse* toward new ideas and new lines of investigation, or, on the other hand, what he actually *held* in the *General Theory*. Thus Professor Hansen says: "Keynes, however, contributed greatly to the theory of the rate of interest. As a result of his analysis we now place less emphasis than formerly on the rate of interest as a means of increasing the volume of investment" (p. 138). In other words, although Keynes put interest at the very center of his theory, he "contributed greatly" because we now recognize the limited efficacy of interest rates. On the other hand, Leontief rather more candidly writes in general appraisal of Keynes: "He seemed to press, however, for reconstruction of the whole foundation in order to mend a leaky roof" (p. 242).

Furthermore, even so far as concerns the *impulse* to new ideas, one has to consider the contributions made by Keynes' contemporaries, pre-eminently D. H. Robertson—contributions too frequently attributed in the current literature simply to Keynes alone. A re-reading of the Macmillan report, for example, reveals the extent to which Keynes' ideas were anticipated by Robertson.

The New Economics is set together from ten chapters and a Keynes bibliography contributed by the editor, seventeen items available from earlier sources, and nineteen essays (beside the editor's) written for the occasion. For one not conversant with the literature it would be difficult to identify new and old, since no indication of old sources is given in the main text;

* The author is professor of economics at the University of California, Berkeley.

¹ *The New Economics—Keynes' Influence on Theory and Public Policy*. Edited by Seymour E. Harris. (New York: Alfred A. Knopf. 1947. Pp. xxii, 686. \$4.50.)

² Not including those written by the editor.

instead, acknowledgments are made all together on page viii, and reprinted items frequently appear under somewhat altered titles. The present review will not concern itself systematically with either the editor's chapters, or with those reproduced from elsewhere. So far as concerns the former they are intended to "summarize, integrate, and fill in some gaps," but it is doubtful whether this is an appropriate description. So far as concerns the latter, it is convenient to have included Keynes' proposals and addresses pertaining to the Fund, Bank, and British Loan, and also such early systematic explanations and espousals of the *General Theory* as Lerner's, Harrod's, and Meade's. Early restatements which were coupled with largely adverse criticism have not been included, as for example: Hansen in the 1936 *Journal of Political Economy*, Leontief, Robertson, and Viner in the 1936 *Quarterly Journal of Economics*, and Pigou in the 1936 *Economica*. Since these articles include many points of continuing validity, they would have furthered the reader's appreciation of the character of the Keynesian influence.

But the older articles included are well worth renewed attention; and, of the newly written essays, not more than two or three represent net subtractions from the sum of human knowledge, a number offer careful reviews of the content or evolution of Keynes' own thinking, and several contribute very significantly to particular subjects. Taken as a whole, the volume thus attains a quite high average, and Professor Harris might justifiably regard it as the high point of his career as editor. Academic economists will profit, as the reviewer has, not only by studying the book, but also having it available for student use. What, specifically, do the new essays offer?

Amongst the first of these essays are two by Professor Hansen, of which the first is moderate in tone and not particularly striking. Keynes contributed, he says, to the realization that a capitalist system does not tend automatically to sufficient effective demand; and since Hansen also stresses the error of making too sharp a dividing line between pre-Keynesian and Keynesian economics, he would probably not wish to imply that insufficient demand was not a major concern of "business-cycle" theorists prior to Keynes. Keynes also emphasized the dependence of many economic variables upon income, the unreliability of wage-reductions to extend employment, and the possibility that increasing liquidity may not increase consumption. In these points Hansen seems to set forth matters of fairly common accord. But if the consumption function represents Keynes' main contribution, as Hansen maintains, he fails to explain why it is so. He says (p. 137) that this function (*via* the multiplier) supplies the missing link in the reasoning by which "current realized income . . . is less than the normal or full-employment income by the amount that current investment falls below the potential saving at full employment." This sounds very much like the "Fundamental Law" and seems to link unemployment to higher savings as income expands. And yet, so far as concerns secular developments, Hansen very clearly denies the multiplier (consumption function) direction of causation from consumption to level of income and maintains the opposite: "the rising standard [of

consumption] follows the rising income, not the other way around." Is the reverse true for the short run?

Having taken pains in the first essay to demonstrate that a fall of the *rate of interest* does little to expand employment (p. 139), and having emphasized that increased liquidity may be relatively ineffective (p. 151), Hansen reverses himself implicitly when in a second essay he says of money wage reductions: "That so clumsy a method of *securing a low rate of interest* and a relative increase in liquid assets should command the attention of able economists in a modern society equipped with a stream-lined central banking system is a mystery which I am unable to solve" (pp. 201-2, italics mine). Is the system "stream-lined" because its low interest rates have no significant result? In this chapter also there is a long and confused footnote in which Hansen apparently objects to anyone's saying, even if one uses Robertson's periods, that if "excess savings" were tapped and invested, income would not fall. In Robertsonian terms, if savings exceed investment, hoards increase (or bank-loans are repaid). Hoarded sums are by no means limited to current hoarding, as Hansen implies, and current hoarding, by the conversion of illiquid assets into liquid assets, is by no means limited to current income, as he also implies; in a depression, hoards are not apt, therefore, to be "extremely small," as he states. Contrary also to his contention, "idle funds" are quite properly described as an evil. In depression, they are the outgrowth of liquidity preference; and in the postwar period (in which the idle funds stemmed from wartime rationing and not "preference" in any significant sense), they have confronted the various countries with the alternatives of continued controls with suppressed inflation, or of actual inflation. Professor Hansen's miscarried originality when he attempts to think in terms of velocity and cash-balances does not lend much effect to his immoderate language in characterizing this approach as a "curious contraption from the horse and buggy stage" (p. 201).

General appraisal of Keynes' work as a whole and the *General Theory* specifically is essayed also in newly written but very brief papers by Harrod, Copland, and Tinbergen; and in more extended and noteworthy contributions by Haberler and Leontief. Harrod's short review of Keynes' chief works throws into a clear light the fact that "Whatever the final verdict on the *General Theory*, Keynes' greatness as an economist will not be questioned"; Professor Copland stresses the substantial influence of Keynes on public policy in Australia; and Tinbergen shows how readily Keynesian concepts fit into econometric analysis.

Haberler, Leontief, and, in a later context, Smithies are really the only contributors to the volume who attempt systematic criticism of the pure theory of the *General Theory*; and their essays are amongst the best for theoretical acumen. Haberler says (as the reviewer has long believed) that "Keynes' great contribution was that he strongly emphasized the income factor and used it much more systematically in the analysis of economic change than had ever been done before" (p. 166). Aggregative analysis had already been successfully pursued by most business cycle theorists, before

1936, and the marginal efficiency of capital analysis follows conventional lines. Liquidity preference theory, which had been substantially advanced by the *Treatise*, suffered a setback in the *General Theory* by virtue of its making the actual holding of idle balances (L_2) solely the result of anticipations of a *rise* in interest rates.³ Haberler questions the realism of the idea of under-employment *equilibrium* and adumbrates future lines of analysis which will prove more fruitful than the static equilibrium device. At bottom the Keynesian *impasse*, or under-employment equilibrium, rests upon (a) the possibility of absolutely elastic liquidity preference, or (b) highly inelastic investment propensities, both with reference to the rate of interest. In the short run, says Haberler, these do not produce equilibrium, but a progressive tendency of prices, wages (and also employment, I would add) to fall. Actually the short-run under-employment equilibrium would result from adverse *shifts* of Keynesian schedules in ways not covered by his system; and in the long run, the assumed unfavorable elasticities can scarcely be expected to persist. Haberler regards Keynes' refutation of Say's Law as killing dead horses: "hardly any neo-classical economist who ever wrote on money or the business cycle thought that Say's Law did hold in reality" (p. 174). In sum, though the *General Theory* is a new milestone, it does not constitute a revolution of economic theory. A contrary impression might be conveyed by the "excessive and untenable claims made by Keynes and his followers," and by the adherence of a socialist or radical wing. Haberler, however, believes that Keynes himself belonged to the opposed or liberal wing, and this judgment is reflected also in Harrod's essay (pp. 71-72).

Leontief concerns himself with the two principal differences between the classical and Keynesian systems: their divergent assumptions regarding the *supply of labor* and the *demand for money*. While the classical supply curve of labor is a function of *real* wage rates, Keynes' is a function of *money* wages, of perfect elasticity and with no labor forthcoming at a lower level, as would result from a minimum wage law. Unlike the classical function, which fits into the general framework of utility functions, Keynes' function is an arbitrarily assumed, exogenous element (pp. 233-37). To make it compatible with accepted ideas of utility or indifference functions in the field of value theory generally, one would need to reconstruct the Keynesian curve by making it depend on both relative and absolute prices and wage rates. Then *all other* demand and supply functions will have to depend on a price and wage-rate variable; and thus by increasing the number of variables necessary to explain a given phenomenon, the Keynesian approach becomes less general than the classical system. The disastrous consequence of this reconstruction is, however, that if *labor* is guided by the purchasing power of money income in bargaining for money wages, the Keynesian involuntary unemployment disappears. Thus the explanation appears for his "insistence on universal validity of an apparently quite special assumption," the horizontal labor supply function.

³ William Fellner has stressed the improbability of such anticipations in depression; cf. *Monetary Policies and Full Employment* (1946), Chap. V.

But even this special assumption would not produce involuntary unemployment if the horizontal supply line intersected demand at a wage equal to or greater than that required by the supply curve in real terms. If the intersection of the monetary labor-supply and labor-demand schedules rested below this level, both schedules could be raised bodily by reducing the purchasing power of money: involuntary unemployment would be eliminated.⁴ To prevent this outcome, Keynes introduces a theory of automatic hoards as the result of infinite elasticity of the demand for money with respect to interest. The price level cannot be raised because monetary injections will pass into idle balances, an assumption—Leontief might have added—required also by the Keynesian finite cumulative multiplier.

Proceeding from these general appraisals, *The New Economics* devotes separate parts to International Economic Relations, Economic Fluctuations and Fiscal Policies, Money and Prices, and Effective Demand and Wages, each of them including notable new essays. Arthur Bloomfield provides a scholarly summary of Keynes' positive contributions in his various books to exchange rate theory and their implications for the International Monetary Fund. Keynes undoubtedly induced a desirable scepticism with respect to devaluation as an infallible cure of deficits, especially in the short run; and it may be useful for certain purposes to regard "fundamental equilibrium" in the balance of payments as implying full employment in the home economy. Hinshaw's short chapter shows clearly that, though Keynes occasionally seemed to verge upon economic insularity, fundamentally and finally he held that direct intervention devices "will work better and we shall need them less, if the classical medicine is also at work" (quoted on p. 322).

The longest chapter in the book and certainly one of the most profitable is Ragnar Nurkse's analysis of "Domestic and International Equilibrium" (pp. 264-92). Substantiating a view expressed earlier in the present review that the outstanding merit of the *General Theory* is its dramatic emphasis upon income, Nurkse finds the great contribution of Keynesian economics to international trade theory to be its illumination of the income and employment variables in international equilibrium problems (p. 268). Indeed, since these variables were certainly important in the thinking of other economists than Keynes so far as concerns domestic fluctuations, I might hazard the guess that Keynes' ultimate contribution will prove greatest in international economic theory, which had been singularly preoccupied with the allocation of resources and price (rather than income) elasticities. Not much of the new economics under this subject appears in the *General Theory*, but the great impulse to the reformulation of international money and trade theory clearly proceeds from this quarter.

If "fundamental equilibrium" is extended to include full employment, Nurkse takes the necessary further step of including also an absence of price

⁴ Leontief might have pointed out that not only is this the necessary implication of the Keynesian supply function, but also that it is exactly what Keynes describes as the cure of involuntary unemployment in the formal definition of the concept; cf. *General Theory*, p. 15.

inflation or deflation (p. 272). He sharpens the new theoretical tools in a precise footnote on the relation of marginal propensity to import and income elasticity of imports (p. 270, n. 8); and he provides a good conceptual test of aggressive and justifiable commercial and exchange-rate policies. Carrying forward the emphasis of *International Currency Experience* upon the crucial importance of international currency reserves, Nurkse demonstrates the necessity of international cooperation to achieve high employment levels and international equilibrium. Like Hinshaw, he presents evidence that Keynes, unlike some of his extremist disciples, regarded currency rationing, bilateralism, protective tariffs, etc., as temporary and unwelcome expedients: basically he was "the true internationalist among modern economists" (p. 285).

In view of the central problems of the *General Theory*, it is appropriate that the editor evoked for "Economic Fluctuations and Trends and Fiscal Policy" six new essays, the largest number in any part. Albert G. Hart, dealing with "Keynes' Analysis of Expectations and Uncertainty," points out that the *Treatise* introduces anticipations only on special occasions, while the later book makes them central to all economic decisions. Specifically, Hart regards as substantive contributions: the speculative motive for holding money, the analysis of forward markets (in the *Treatise*), the marginal efficiency of capital as a psychological phenomenon, and role of "animal spirits" in entrepreneurial decisions. On the other hand, he finds that Keynes confused *ex ante* and *ex post* values, neglected short-term expectations (?), failed to appreciate differences of degree in liquidity of assets, and utilized the dubious device of reducing true contingencies to certainty equivalents. Hart concludes with a warning to followers of Keynes against neglecting the increase of business uncertainty which may attend economic intervention.

In discussing "Declining Investment Opportunity," Alan Sweezy reviews the evolution of the thesis and offers some reasonable objections to crude misinterpretations. To test the thesis formally, however, he proposes a model in which "there are no new inventions, no shifts in demand, no new resources to exploit; in short, no outlets for investment except in providing more equipment of existing types and more working capital for the increment of population" (p. 433). Sweezy regards this model as one designed "to simplify the problem." But actually in the phrases before the semicolon, he selects imaginable though improbable circumstances most apt to result in stagnation of investment. On a formal plane, however, he commits two errors even on this favorable terrain. In the first place, it does not require new inventions in order that capital be substituted for labor, and hence the "equipment of existing types" following the semicolon is a *non sequitur*. This is particularly striking since he himself envisages the outcome of his model to be a rise in real wages and a fall in "profits" (in the classical sense). Secondly, he represents the possible consequences of the fall of "profits" to an unsatisfactory level to be either reduced saving or the (indefinite) holding of savings in liquid form. The latter solution, however, would have to meet Hart's objection that "if the growth of cash relative to income is capable of affecting the propensity to consume in the slightest degree, it can generate experiences

which will justify raising estimates of money receipts from equity assets" (p. 421).

"Keynes and the Theory of Business Cycles," by Lloyd Metzler, presents the view that Keynes was responsible for refuting (1) "the usual assumption amongst more analytically minded economists . . . that the economic system tends automatically toward a state of full employment" (p. 438), and (2) Say's Law, which "leads to the conception of the economy as an unstable system *in which a slight contraction leads to further contraction*, and a slight expansion set off a cumulative upward movement" (pp. 442-33, italics supplied). Sufficient evidence could be marshalled, the reviewer believes, that the "more analytically minded economists" who considered the problem of business cycles prior to the *General Theory*, e.g., Keynes himself, Robertson, Pigou, Hawtrey, Schumpeter, Mitchell, and so on indefinitely, held neither (1) that the economic system tends automatically toward full employment, nor (2) Say's Law. This exercise will prove superfluous, however, if the author will reconsider his charge against the "more analytically minded economists" under heading (1), in the light of what he says about them under heading (2), and *vice versa*.

One of the most illuminating and judicious essays of the volume, on "Fiscal Policy," emanates from Gerhard Colm. While profoundly affecting the views of economists and legislators as to the virtues of a balanced budget, Keynes did not give exclusive attention to fiscal policy as a means of combating depression; and Colm himself believes that "flexibility in the Federal budget is limited," although "our legislative and administrative machinery is not yet fully equipped to use even this limited existing flexibility" (p. 464). For those who, like the present writer, would like to see the *first* (but not *last*) fiscal line of defense against inflation and deflation in direct variations in federal revenue, rather than in inverse variations in federal expenditures, it would pay not to lose sight of Colm's warning that "the multipliers applicable to a reduction in income taxes which are already nearer the maximum rate of progression is relatively small" (p. 465). This implies that combating inflation by *fiscal* (as opposed, say, to monetary) devices has to bear more severely on the low-bracket incomes. Colm believes that Keynes slighted cost-price relations as determinants of investment and consumption; "additional government investments can hardly be regarded as the most rational cure when excessive prices or costs [arising, he explains, from excessive monopolistic prices or too rapid an increase in wage rates] are the cause of a disturbance" (p. 457). As for the opposite extreme of fluctuation, "it may well be that the first recession after the postwar boom may be of a nature that requires first of all measures designed to adjust costs and prices in relation to incomes, rather than fiscal policies" (p. 467).

Whereas Colm believes that "there has been a growing recognition of the practical limits of a public-works policy as an anticyclical device" (p. 464), Benjamin Higgins, in an essay devoted to this subject, maintains that the *General Theory* has elevated public investment "from the rank of last line of defense to major offensive strategy" (p. 474). Keynes' *opus* despaired of

stimulating private investment, at least in the long run, and hence gave about coordinate importance to raising the propensity to consume and to public investment (pp. 474-75). Higgins, however, regards the former as more promising as a secular than as a countercyclical device, and hence concludes that "public investment is left virtually in sole possession of the field, when it comes to policies for offsetting fluctuations in private investment" (p. 476).⁵ With respect to leaf-raking varieties of Keynesian "investment," Higgins supplies an interesting proof that "the useful projects will have greater multiplier effects just by the value of the direct services they yield" (p. 479).

The last chapter devoted to fluctuations is by Richard M. Goodwin on the multiplier. This essay raises a substantial number of difficulties. Is it a fact that Angell gives the income velocity of *active* money a value around 3 per annum (p. 488)? If newly created money comes to be divided between active and idle in same proportion as prevailed before the injection, will not velocity remain constant (*cf. General Theory*, p. 306); or is velocity constant *only* if all the new active money is newly created money, and if there was no idle money before (Goodwin, p. 492)? The multiplier, telling "by how much the original injection is multiplied to obtain the final result" on income, gives "the typical life history of any dollar spent . . . from birth to death" (p. 484). If *any* dollar spent typically "dies," why are not *all* dollars sooner or later "dead"; or is it just the "injection," no more and no less, which dies? If, following the author's practice, all spending not out of *income* (consumption or investment from dishoarding or new money) is excluded from the multiplier, can we then say that "it is to the multiplier, not velocity, theory that one has to turn for the explanation of the variations [of income]" (p. 489)? A satisfactory treatment of the relationship between the multiplier and velocity should resolve these and a number of other difficulties involved in the essay.

The Part dealing with "Money and Prices" includes a single paper, contributed by John Lintner. This essay begins by contrasting the highly simplified monetary analysis current in this country during the first World War with the more sophisticated analysis of World War II, which proceeded from more advanced theory and the great boon of fairly complete national income statistics. Part of this advance in theory is attributable to Keynes, whose monetary analysis Lintner traces through the *Tract on Monetary Reform* (1923), the *Treatise on Money* (1931), and the *General Theory*. The *Tract* contributed a clear statement of the Cambridge cash-balance theory, but labored under the handicaps of: (1) tracing relations between money and prices on the assumption of constant output; (2) neglecting the precautionary motive for holding money; (3) lumping all groups of money holders together.

The *Treatise* eliminated the second and third of these limitations, considerably advanced the explanation of motives for holding money, and drew some illuminating distinctions between the behavior of various groups of cash-

⁵ It is not clear whether Higgins means this literally, including tax-structure, revenue reduction, cost-pure relations, etc., or only relatively to varying consumption.

balance owners. Indeed, the *Treatise* reached a plane of monetary analysis superior to the *General Theory* in a substantial number of respects. The *Treatise* laid weight upon *shifts* in liquidity preference, while the later book attempted pretty much to operate along a given liquidity function. The *Treatise* emphasized the dependence of idle balances on the yield of all types of earning assets, while the *General Theory* operates in the narrow confines of cash *vs.* bonds. While the later work treats all balance holders alike, the former distinguished forms and individuals. The *General Theory* must also be taxed with engendering confusion as to the necessarily-equal and not-necessarily-equal meanings of saving and investment.

What the *General Theory* accomplished, over the yield of earlier works, was the integration of output (income) variation into a general equilibrium system. Lintner believes that an analysis running in terms of liquidity preference, marginal efficiency, and the multiplier determined by the propensity to consume is a much more powerful apparatus than analysis in terms of "the one 'blanket' factor V" (p. 532). While I also would prefer three variables to one, I do not believe the alternatives are necessarily those thus stated. And who has, as a matter of fact, explained variations of output in terms solely of V?

We turn to the last group of contributed essays, consisting of two by Arthur Smithies and James Tobin. While the caption given to this Part is "Effective Demand and Wages," Smithies' paper really offers a succinct statement of the whole Keynesian and the contrasting "classical" system, and a general critique of the former. For comprehensive statement within economical confines and for genuine theoretical acumen, the essay is unrivalled. I shall not reproduce Smithies' reproduction of the Keynesian and "classical" systems but emphasize his critical and suggestive efforts "Toward a More General Theory." Taking the *General Theory* as a valuable achievement, he believes that it must be amended or broadened in the following respects. (1) Keynes' assumption of constant equipment must be revised to include a theory of the optimum rate of accumulation; and his assumption of constant techniques must give way to a theory which recognizes substitution of factors. (2) Keynes omits consideration of the adjustment *vs.* the equilibrium effects of changes in effective demand. (Technological unemployment would afford a good illustration.) (3) His assumption of perfect competition lets the following possibilities escape attention: that, with decreasing costs under monopoly, employment and real wages can both increase *within a range*; that reducing monopoly restriction may increase both employment and real wages; and that bilateral monopoly between labor and business may produce a full-employment dilemma. (4) The Keynesian assumption that real income and employment are determined independently of wages and prices ignores that as the latter rise, progressive income taxes give a revenue increase proportionally greater than the wage-price advance, and the fixed money commitments (interest, etc.) produce an expenditure increase which is proportionally less. (5) In an economy with mobility of resources and the price of imports and exports established in world markets, *money* wage rates would determine real wages and employment. Keynes' contrary conclusions

rest upon his assumption of a closed economy. The theoretical reconciliation of these two possibilities with Keynes' opposition to restrictive commercial policy has not been worked out. (6) Aggregative theory neglects the whole yield of "classical" theorizing as to the bearing of relative wages and prices and the allocation of resources upon output and employment as a whole. (7) Dynamic factors exogenous to the Keynesian theory require recognition and elaboration: the wage increases of 1937 contributed to the subsequent depression; low profits may influence plans and later investment rates; consumer demand may not be a function of current income alone, but also of expectations as to future prices, etc. In sum, "the *General Theory* is a most constructive tool for those who are aware of its limitations, but a dangerous one for those who ignore them" (p. 569).

Finally, we must consider all too briefly the brilliant essay by James Tobin on "Money Wage Rates and Employment." Like Leontief, Tobin argues that Keynes is wrong in representing the volume of employment as independent of money wages. Both would apparently agree that the Keynesian position is wrong (1) if *all* factors including labor are supplied with reference to the purchasing power of money, or (2) if they *all* are equally victims of the "money illusion" and bargain solely in money terms. Leontief argues that a real calculus is probable for all factors, whereas Tobin believes that there are good reasons for supposing that labor bargains in money terms (p. 581) and for the same supposition for other factors (p. 582). Since it is a lack of homogeneity on this score which Keynes' position requires, both agree in the final outcome. Furthermore, both agree that real consumption cannot be uniquely a function of real income, as Keynes would have it; Leontief would say, because consumers look beyond prices, as all factor owners do; Tobin would say, because consumers do not look beyond prices, and all factors do not (pp. 583-85). Here again both agree that the Keynesian position on the consumption function cannot be maintained if a "homogeneous" assumption is maintained with regard to attitudes toward money and real values. Tobin elaborates still further reasons for rejecting the Keynesian position and summarizes his case under six possible channels through which money wages can affect employment: (1) business confidence; (2) the balance of trade; (3) the demand for cash balances; (4) induced substitution of labor; (5) demand for consumption goods; and (6) redistribution of income. Of these, Leontief does not treat (1) and (6), explicitly argues also on the basis of (3), (4), and (5), and implicitly includes (2).

A laborious notation of every omission, every misconceived statement, every example of over- or underestimation of importance, and every wrong assessment of the facts would make a formidable array against almost any economist, even those of greatest stature. Thus Keynes' tendency to belittle his predecessors and even to misrepresent their views has undoubtedly damaged his own reputation. His lashing out against Say's Law makes him seem ignorant of the fact that it was not designed by its author to shed light on economic fluctuations, and was not so employed by his own immediate predecessors. His own confusion as between *ex ante* and *ex post* led to a

breakdown of reasoning in crucial passages in the *General Theory* and precipitated much blood-letting, when a clear statement of these contrasting (and reconcilable) views of saving and investment had been worked out by Myrdal, Ohlin, and other Swedish economists several years prior to the publication of Keynes' book. Involuntary employment is formally defined in terms of what Keynes thought to be a remedy; and the abstruseness of the language concealed the fact that this remedy was the Machiavellian device of watering down wages by inflation.

All of these are side issues. The significant question is: what in the *central theoretical body* of the *General Theory* now survives in a fairly intact form? The present volume gives additional evidence that a number of its most central ideas have been abandoned or reformulated to a state almost beyond recognition from the original. This holds true in pre-eminent degree of the thesis that a change in money wages cannot alter employment. As a matter of fact, the ways in which it *can* alter employment are so numerous as to cause the thesis to be altered to the form that wage-reduction cannot in many instances be relied upon to extend employment because the multiplicity of possible reactions makes the outcome obscure. By parity of reasoning, in some situations with a few conspicuous variables, the outcome (either way) might be predicted. This is no longer Keynes.

Much of the plausibility of under-employment equilibrium (or of an automatic *impasse* in the capitalistic system) came from Keynes' making L_2 ("speculative" balances) a function solely of anticipations as to the rate of interest. But in a depression people would behave irrationally if they expected interest rates to rise and if for this reason they absorbed money indefinitely. It is now definitely established that expectations as to capital *yields* are more important than expectations as to capital *costs*; and hence the holding of idle balances answers to all the multiplicity of forces usually discussed under "the lower turning point." This outcome is, again, quite alien to the few variables of the Keynesian system; and it may undermine the idea of under-employment *equilibrium* even with the introduction of substantially more variables.

It is usually said that Keynes' "marginal efficiency of capital" is the traditional productivity theory with the needed addition of emphasis upon anticipations. Actually, Keynes altered the productivity theory very radically, and in a direction favorable to underemployment (of capital or of labor, whichever suited the occasion), by the assumption of fixed techniques. Several authors in the present volume point out the arbitrariness of this assumption past a very short run. Thus another factor in addition to flexible real wages is rehabilitated from the "classical" limbo to permit factor substitution and equilibrium.

A fourth respect in which current judgments, reflected in the present volume, run quite counter to the central core of the *General Theory* pertains to the significance of the cost-price structure for such aggregates as output, savings, and employment. The central Keynesian system of five large variables has no place for the bearing of allocation of factors as it occurs in such manifold forms as the tax structure, the directions of public expenditure,

the role of monopoly *vs.* competition, the effect of inflation and deflation on productive efficiency, etc. Thus, much of the valuable yield of "classical" economics, business cycle theory, monetary theory, and the analysis of taxation is shut out in the particular macro-economic system of the *General Theory*. It is really far short of generality.

With the noteworthy exception of the consumption function (and multiplier) yet to be considered, the preceding points cover the formal Keynesian theorems. It is, I believe, not unfair to say that, however great the impulse given to economic theory by Keynes—and this beyond dispute—the formal theorems have been rejected or extensively modified. What then of the positive theoretical yield? Are there gains which would be as generally accepted as the corrections and negations appearing in *The New Economics*; and how important are they? I will not attempt to select "the" great contribution, for there are several and only the future will reveal their relative importance: the macro-economic approach, the effective introduction of income as a variable of primary importance, the degree to which interest rates respond to monetary forces, the effective demand aspect of wages, the possible miscarriage of savings. Some of these are matters of emphasis rather than theoretical discovery, but the emphasis virtually amounted to discovery. In the aggregate this is a very great yield, enough to support Keynes' reputation, great as it is, and great enough without effort to justify his errors.

Of the central theoretical core, virtually the only innovation which seems to meet with general acceptance is the consumption function (sometimes with, sometimes without, reference to the related multiplier). Harris regards it as an outstanding contribution (p. 26), Hansen as "epoch-making" (p. 135), Samuelson as vitally important (p. 159), Tinbergen and Higgins, as Keynes' main contribution (pp. 222, 564); and Haberler, while expressing the opinion that it is "overworked" and too rigidly formulated, thinks it represents a salutary shift of emphasis toward income (p. 166). Only Colm raises a note of scepticism, holding that the consumption function is less reliable for *predictions* than "sample studies of business and consumer attitudes" (pp. 460-61), an opinion expressed outside the present volume by Smithies.

But what is the consumption function? None of the writers just referred to defines or describes it, incidentally to bestowing praise. Hansen, indeed, explains that both the configuration *and* the shifts of the consumption function depend on income (pp. 138-39); and Tinbergen suggests that individual consumption expenditures are functions of "individual incomes, a number of price variables, the size of all families involved; and, perhaps, other factors" (p. 223). But it is not easy to see how these explanations illuminate the character of the function in most of the explanatory values assigned to it. Indeed, the consumption function seems to resemble the Holy Ghost: a derogatory attitude toward it is the ultimate sin, but precise information about it is hard to come by. Keynes' own statement of its properties, as given on page 190, follows: "It simply amounts to saying that an increase in income will be divided in some proportion or another between spending and saving, and that when our income is increased it is extremely unlikely

that this will have the effect of making us either spend less or save less than before." From these descriptions it is not clear how the consumption function, as Professor Harris says (p. 52), "helps to explain why all goods produced are not sold (as suggested by Say's Law); the declining marginal efficiency of capital; the theory of secular stagnation (Sweezy); the independence of changes in wage rates and employment (Tobin); the theory of the trade cycle (Metzler)."

Each of these may be the subject of some justifiable scepticism. Thus, (1) the failure of goods to be sold, a cyclical phenomenon, was coupled by Keynes himself with a collapse of the marginal efficiency of capital; and since *ex ante* investment more than makes up for the gap between income and consumption, it does not seem possible to derive a downturn from the lag of consumption except by appeal to the acceleration principle—but this is not the consumption function. (2) The declining marginal efficiency of capital could be explained by the consumption function only on the assumption of some "necessary" relation of investment to consumption. There is no such necessary relation; and Keynes himself, as Lintner emphasizes in the present volume, made fluctuations in autonomous investment, both in the *Treatise* and *General Theory*, to be the primary initiating cause of change (p. 523). (3) Statistical evidence does not suggest a secular decline of consumption relatively to income. But aside from this, the existence of "secular stagnation" is still a moot issue, as well as its theoretical foundation. In passing, Hansen did not appeal to the consumption function in his own explanations of stagnation. (4) This point may be dismissed, since Keynes did not connect the neutrality of money wages as to employment with the consumption function, and Tobin argues for the *dependence*, not independence as Harris says, of employment on wages. (5) The cyclical role of the consumption function is an involved issue. Some indication of the divergence of views on this subject may be gathered from a contrast of Metzler's belief that the upper and lower turning points are *explained* by the consumption function with Bean's view, which emphasizes "the business cycle in addition to disposable income as a *factor in determining* consumer expenditures (italics supplied)."⁶

The new economics, undoubtedly inspired by the influence of Keynes, is making rapid strides; but the rapid strides are fast leaving the *General Theory* behind. There has been a glorious revolution but, after the way of revolutions, it has both its glorious and its ignominious sides.

EQUILIBRIUM OF THE FIRM

By RICHARD A. LESTER*

The articles by Professors R. A. Gordon and L. G. Reynolds in the June, 1948 issue of this *Review*¹ contribute considerably to clarification and resolution of some of the issues in what has come to be known as the "marginalist controversy." This note will be confined to comment on three matters discussed in those articles, *viz.*, the character of marginal variable costs, the nature of demand to the firm, and long-run goals of business management. They are all involved in a consideration of equilibrium of the firm.

I

On the assumption that a horizontal labor supply curve and constant supply prices for materials are the most common conditions, Professor Reynolds believes it "reasonable to expect constant marginal cost as the typical situation."² He suggests that my results indicating that business executives seem typically to think in terms of a downward-sloping, marginal variable cost curve up to designed capacity of the plant may be due to the possibility that the reporting executives included in their estimates certain groups of "semi-variable costs" such as "indirect labor." Undoubtedly many of them did.

In considering this question it is helpful to distinguish between changes in marginal variable cost that accompany (1) a decline in the scale of plant operations, (2) an increase in the scale that only involves more employment within the normal work week for employees that have continued to work or the re-employment of employees who had been laid off but a short period of time, and (3) an increase that necessitates the hiring of new employees, the recall of employees away from the job for a considerable period, or the purchase of additional overtime hours.

Plants are ordinarily designed and equipped so that at (or possibly even slightly above) capacity operations³ there should exist the most efficient flow

*The author is professor of economics at Princeton University.

² *Loc. cit.*, p. 295.

³ Businessmen generally seem to think of plant capacity in physical terms, as equipment capacity with full-crew operations at some given standard, usually a level of achievement attained a number of times in the past and somewhat short of maximum conceivable output under ideal conditions with full-crew operations. It is the output for which the plant and equipment were designed, assuming some "normal" rate of efficiency and the regular number of shifts. That is the concept used here. Admittedly it is not as exact as one would desire. Presumably plant capacity so defined would vary somewhat with operating conditions such as the quality of materials, the product-mix, and the extent to which maintenance is temporarily deferred. Businessmen do not appear generally to think of capacity in the theorists' terms of the low point of the total unit cost curve, which would

of materials, the most effective use of transport and other services, the best runs of a production item, and so forth. A general reduction in the scale of operations below capacity would usually mean more time on set-up operations per unit of output with shorter runs, transfer and less effective distribution of personnel (probably according to the seniority provisions of a labor agreement), and, often, reduced employee morale and perhaps output restriction to make the job last, as the result of lay-offs and part-time work.⁴ Consequently, the direct labor cost per unit of output would be likely to rise. Other less direct costs per unit of output would also tend to increase, such as the employer's unemployment-compensation tax rate under experience rating and his outlays for employee welfare or benefit plans per dollar of payroll. Furthermore, reduced plant output, if significant in size and continued any length of time, would mean smaller quantity purchases of electric power, materials, and parts, which usually would be at higher unit prices and at higher unit transportation and handling costs for supplies. Shorter runs are generally at higher unit costs for the parts supplier.

Although there are good grounds for believing that increasing variable unit costs frequently accompany a required reduction in the scale of plant operations below capacity (especially under a union contract with seniority governing lay-offs and transfers and with superseniority for shop stewards), not all of those grounds apply with equal force in the opposite direction. That is true even for an increase in operations toward plant capacity that would involve only reducing part-time employment or recalling recently laid-off employees. In the latter case, for example, numerous transfers of workers under the seniority provisions would undoubtedly be required, and one could hardly expect employee morale to increase above normal by as much as it might decline with curtailed operations. Also, with such matters as employee transfers and morale involved, the time element becomes significant. Unit marginal cost may be somewhat larger immediately after the reduction or increase in scale of plant operations occurs from what it would be after the reduction or increase had been in effect for a period of time. The dynamic aspects of unit variable costs are a relatively unexplored area.

II

The authors of the two articles point out that in the short run the businessman is more concerned with sales estimates at a given price than he is in the shape of the demand curve at any particular moment,⁵ and that over short

vary with the character of the labor force, overtime and other provisions of labor agreements, etc.

⁴ The method of wage payment might make some difference. To the extent that hours of direct labor are paid at piece rates, labor costs would be constant per unit of output. However, even in piece-rate industries a considerable portion of direct labor cost in any one pay period will be paid for on a non-piece-rate basis (usually for work under non-standard conditions, for set-up operations and down-time, for new work before a piece rate is established, for jobs that do not lend themselves to the piece-rate method of payment, and for workers transferred from their regular jobs).

⁵ Gordon, *loc. cit.*, p. 277.

periods the scale of output is based primarily on anticipated movements of demand, which are largely independent of the employer's price decisions or current cost conditions.⁶ That is the point I have stressed.⁷ Professor Reynolds adds in a footnote (p. 305) that the kinds of estimates which businessmen actually make, such as expected sales volume, output, and level of unit costs, are probably best visualized as single points on the price-quantity diagram; as they do not seem to think in terms of continuous curves or schedules.

In a recent note,⁸ I discussed the absence of subjective demand schedules for firms that persistently conform to the price leadership of other firms or that produce items whose price remains unchanged for a number of years. For such firms, the selling prices of products are assumed by the management to be determined by factors outside the control of that firm. It is obvious that price-following firms and producers of articles with customary and constant prices do not frequently and seriously speculate regarding the elasticity of demand to the firm for each of its products. The terms "point demand" or "single-quantity demand" can be used to characterize subjective demand as visualized by a price follower or a fixed-price producer for a particular time interval. An executive in such a firm thinks in terms of the expected sales of each of his products distributed over time intervals, a certain total for the next week, month, or quarter, another total for the succeeding interval, and so forth, over the ensuing year or whatever his short-run planning period may be. For each interval of the planning period he anticipates a certain amount, or, less likely, his estimates may take the form of a range, with different probabilities for various areas within the range. Such interval estimates may, of course, be revised as experience indicates.

A demand curve cannot be derived by connecting the series of weekly, monthly, or quarterly point demands, nor can one consider as a demand curve a range of estimated possible sales for any one time interval, or the path of any alterations in the estimates of demand for a particular interval, or the difference between expected sales and later realized sales for a time interval.

It has been contended that, instead of a point, the demand to (say) a price-following firm should be considered to be a schedule in the form of a straight horizontal line at the given price and extending in both directions from the firm's estimated quantity of sales for a time interval. That, however, is unwarranted. It assumes that the management is thinking in terms of having orders in excess of expectations or of refusing to accept varying amounts of expected sales, which certainly would not be likely unless it was operating at or above the designed capacity of its own plant facilities and could not contract out the work except at a money loss or with some deterioration in quality of product. As businessmen aver, the management of each firm in a manufacturing industry strives to maintain or improve the firm's market

⁶ Reynolds, *loc. cit.*, pp. 297 and 304.

⁷ See, "Marginalism, Minimum Wages, and Labor Markets," *Am. Econ. Rev.*, Vol. XXXVII, No. 1 (March, 1947), pp. 138 and 148.

position, usually measured by the percentage that its sales bear to total sales of the product in the markets where the firm is one of the suppliers. A management would not think of deliberately sacrificing its market position by refusing offered business; manufacturers have learned that loss of position for any reason, including lack of capacity in boom times, is usually difficult and costly to recover later.

From time to time a firm may, of course, change with respect to one or more of its products from a condition of point demand to some sort of schedule of demand and vice versa. The prices of even price leaders may be fairly fixed over short periods of time, such as a "season" or "model year." Manufacturers of such branded items as men's and women's clothing, household electrical equipment, automobiles, construction machinery, and numerous "catalogue" items, normally may not anticipate or consider any change of price during a period of at least six months to a year. Customarily the period of any price change for them may be only a minor fraction of the year, during which only one set of price changes occurs. For the remainder of the year, a condition of point demand may prevail.

The management of a firm may, when pressed by rising costs, shortage of liquid assets, or loss of market position, begin to consider the possibility or necessity of price cutting, including secret concessions from its quoted prices. Whenever the management begins to include the possibility of relative price changes on its part in its planning, it is, so to speak, shifting from point demand to some sort of demand schedule. Instead of price change, however, the management may seek to meet its difficulties by non-price means such as improved sales methods, shifting output between price and product lines so as to increase its sales in lines likely to be most favorable, redesigning its products, or reducing costs per unit of output by such means as improvement in the flow of materials and in the scheduling of production, better use and control of inventory, development of improved production methods and equipment, reduction in material costs of products through content changes, and simplification of paper work. The large possibilities of cost cutting and increasing income without price changes are common knowledge to persons well acquainted with industry but are generally neglected by theorists who reason in rigid, mechanistic terms and disregard human nature. If managements think in terms of making adjustments exclusive of price change, subjective demand for each item may continue to be of the point rather than the schedule variety.

III

The concept of point demand, in conjunction with decreasing (or even constant) marginal variable cost up to and beyond normal plant capacity, would seem to require significant revision of notions regarding equilibrium of the firm. It is doubtful whether business executives generally think, plan, or act in terms of a single equilibrium point, determined separately for each item of production.

One might assume that, under decreasing or constant marginal variable costs and point demand, equilibrium would be at the point of plant capacity.

On testimony of business executives that, however, is questionable. For example, Mr. Frank D. Newbury, former vice president and director of the Westinghouse Electric Company, states that an increasing total unit cost curve between 100 and 120 per cent capacity would be rare in mechanized industry because any increase in unit variable cost that was large enough to more than offset the reduced overhead per unit would be "extraordinary, and would represent inexcusably poor management."⁹

It seems likely that total unit costs are often fairly constant over a range of output, say from 95 to 110 per cent of plant capacity.¹⁰ That might be considered an equilibrium zone in the sense that, within that area, the firm's management would consider its operations satisfactory or reasonably profitable; it would not feel pressed to move outside the zone or to attempt to influence sales so that the firm would arrive at any particular point within the zone. Incidentally, firms will not normally offend respectable customers by rejecting their business, so that there is no regular stopping point beyond which the firm refuses business on the grounds that it is less profitable or even unprofitable. And, under point demand, it would not attempt to keep output at some "equilibrium point" through price manipulations.

In general, the area of satisfactory operations for a company would, on the vertical price scale, be somewhat above the total unit cost curve and, on the output scale, would lie within a range of high outputs. Of course the size and shape of such an "equilibrium zone" would vary from firm to firm and from time to time for the same firm. Whether a firm at any particular time was operating within its satisfactory zone would in large measure be determined by actual and expected demand for its products. Below and to the left of the satisfactory zone would be areas of progressively less satisfactory operations. Generally, a management's efforts both for greater sales and reduced costs would become more energetic, even desperate, the further the rate of production fell below its satisfactory range and also the more the firm was losing its position in various markets to competitors.

The discussion so far has concerned short-run equilibrium. It is proposed that for many companies and conditions the mathematical or mechanistic concept of point equilibrium be replaced by the psychological notion of current and prospective operations within a satisfactory zone. Temporary, short-run equilibrium positions or areas are conceivable outside the satisfactory zone, if the firm's management believes that it is doing the best it can under the circumstances, taking into account such factors as how the firm stands relative to its competitors, what financial pressures are affecting it, and conventions in the industry. For reasons of liquidity or strategy or for

⁹From correspondence and mimeographed material supplied by Mr. Newbury. In contending that total unit costs continue to decline well beyond plant capacity, he points out that plant capacity usually is not a precise figure and that maximum possible output is influenced by such factors as the physical capacity of the major equipment, the actual product-mix, shift and overtime arrangements, and the ability of management to correct bottlenecks as they arise.

¹⁰The possibility of operations at 110 per cent of capacity exists in part because of the definition of capacity adopted in footnote 3 and circumstances mentioned in footnote 9.

current lack of resources, the management may, for the time being, not favor engaging the firm in additional actions and expense to increase its share in the total sales of the industry, although continuing unabated and with an increased sense of urgency such activities as product research, planning to improve sales, and the search for savings in cost.

Some brief comments now on long-run equilibrium. As the primary, long-run objective, especially of mature, successful firms, Professor Gordon suggests "‘satisfactory profits,’ as vague as that criterion is," and a safe financial position.¹¹ My investigations lead to the conclusion that, instead of a single, long-run objective, business managements pursue simultaneously or successively a number of goals, which are not completely consistent with one another. The order of priority may vary from time to time, perhaps changing with conditions facing the firm, so that new balances may have to be drawn between conflicting goals. A list of such goals might include the following: "satisfactory" or "reasonable" profits, maximum possible profits, security and convenience of the existing management, achievement and maintenance of sufficient liquidity to assure the firm's financial safety, and maintenance of the firm's market position or its established share of the industry's total sales.¹²

The particular goals and the management's strength of desire to attain them may vary with the age and degree of maturity of the firm, the management, and the industry; with the extent and kinds of pressure from stockholders, creditors, and labor; and with the attitudes of the community, the customers, the suppliers, the employees, and competitors toward the firm and its management. Attitudes, supported by organizational influences and pressures, may be very influential, especially where the management is sensitive to outside opinion and seeks to avoid difficulties for itself.

It might be contended that some of the goals in the list are means of achieving others rather than themselves being primary objectives. Illustrations of possible conflicts between them indicate, however, that frequently that is not the case. The management of a firm may consider it unwise to have it make a profit beyond a certain total or percentage of stockholders' investment in any one year. That may be because maximum possible profits would result in adverse publicity, would encourage organized labor to use the firm as a wage leader, might lead to governmental investigation and prosecution of the management, or might have some other effects that the management, for non-profit reasons, desires to avoid. Adequate liquidity may be purchased at the continued expense of the possibility of greater profits. The management of a firm may strive to maintain its position and prestige in an industry even though the dropping of some unprofitable lines would promise an indefinite increase in the rate of profit on owners' equity. Insufficient emphasis has

¹¹ *Loc. cit.*, p. 271; see also pp. 275 and 284. Professor Reynolds remarks: "There may be little interest in *maximum* profits so long as actual profits are up to conventional standards" (*loc. cit.*, p. 298).

¹² Professor Gordon refers to some of these as subordinate objectives, although he conceives of them as often independent of the primary objective and he seems to imply that at times they might take precedence over the criterion of profits.

been placed on maintenance of a firm's market position and prevention of any decline in its relative status as an independent motivating force, influencing a company's policies with respect to sales, output, and investment.

Multiplicity of and varying priority in the long-run goals on a firm make all the more questionable the notion of short-run equilibrium at a point uniquely determined, and lend support to the concept of an equilibrium zone or area. Incidentally, some fairly obvious similarities exist between a long-run goal of "satisfactory" profits and short-run zone of satisfactory operations.

The conceptions of long- and short-run equilibrium outlined here may seem so vague and indefinite as to rob the notion of equilibrium of the firm of much of its analytical usefulness. If one is thinking in terms of mathematical precision and manipulation, that may to some extent be true. This psychological approach in terms of management satisfaction and dissatisfaction does, however, appear to conform rather closely to the pattern of business thinking and practice and seems to offer possibilities of fruitful development through empirical investigation. By broadening and shifting the base of analysis it may help to provide keys for a number of doors that until now have remained unlocked.

THE NEW BRITISH LAW ON MONOPOLY

By RUTH COHEN*

The British Monopolies and Restrictive Practises (Inquiry and Control) Act passed the British Parliament, unopposed on its main points, in the summer of 1948. It is the first British statute since the Statute of Monopolies in 1624 for the regulation of monopoly in general (as distinct from the control of the "natural" public utility monopolies). Previously, monopolies were only subject to such control as was provided by the common law. Under this, certain contracts in restraint of trade are illegal and unenforceable; but the exceptions are so large, and the interpretation of the law has been so favourable to agreements that there remain, probably, few monopolistic practises except the most obviously outrageous which are illegal and not many which cannot be so drawn as to be enforceable at law.

This article first outlines the main provisions of the new act and then comments on some of the points of policy involved.

The long title of the act reads "an Act to make provision for inquiry into the existence and effects of, and for dealing with mischiefs resulting from, or arising in connection with, any conditions of monopoly or restriction or other analogous conditions prevailing as respects the supply of, or the application of any process to, goods, buildings or structures, or as respects exports."

The act applies when one-third or more of goods of any description in the United Kingdom or a substantial part of it is supplied, bought or processed, either by or to one person (or by or to interconnected corporations) or by or to two or more persons who have a tacit or expressed arrangement to limit competition in any way in the particular trade. It applies also if, by agreement or arrangement, goods of a particular description are not supplied at all in the country or a substantial part of it (Clauses 3 and 4). Finally it applies to exports, either as a whole or to particular markets, if one-third of British production is in one firm's hands, or subject to arrangements to limit competition (Clause 5). Agreements dealing with wages and employment are exempt from the provisions of the act (Clauses 3, 4, and 5).

A Commission is to be set up, consisting of not less than four nor more than ten persons appointed by the Board of Trade. The normal period of office for any member is intended to be five years, but a member can be reappointed for one further period (Clause 1). This Commission is to examine cases referred to it by the Board of Trade, selected from among those to which it appears the act applies. The Board may not refer cases where the arrangements have been expressly authorized by law (*e.g.*, nationalised industries, Agricultural Marketing Boards). But the Commission may be asked to assist the Board in considering any matter to which this act applies, whether the ar-

* The author is a fellow of and a University lecturer in economics at Newnham College, Cambridge, England.

· rangement in question has been authorised by law or not (Clause 2).

The Board of Trade may refer cases to the Commission in either of two ways: (a) it may limit the investigation and report to the facts, that is to say, to whether the conditions to which the act applies in fact prevail for the goods in question, and if so how and to what extent, and to the actions which the parties concerned take as a result of or in order to preserve those conditions; or (b) it may require investigation and report on both the facts and on whether the situation reported operates, or may be expected to operate, against the public interest (Clause 6). (An attempt, discussed later in this article, is made to define "the public interest" [Clause 14]).

The Commission must report unequivocally and, where the investigation is not confined to the facts, may suggest action, to be taken by Ministers, government departments or the parties concerned, to remedy or prevent anything which, in its view, operates against the public interest. If any member of the Commission dissents from the majority on a reference not confined to investigation of the facts, he may include his views in the report (Clause 7).

Later the Board may ask the Commission to report on how far any remedial action it proposed to the parties concerned is being carried out (Clause 12).

References to the Commission must be published (Clause 6), and the Commission's report must be laid before Parliament if it was not limited to the facts, subject to a security safeguard and to the possibility of suppressing information which substantially damages "legitimate business interests" and which is not vital to the argument of the report. The Board of Trade may decide whether or not to lay before Parliament reports confined to the facts (Clause 9). The Board must also lay annually before Parliament a report reviewing suggestions and requests for reference of matters to the Commission, provided these do not appear to be frivolous (Clause 16).

Finally the Board may ask the Commission for a report on the general effect on the public interest of particular monopolistic and restrictive practices, provided the Commission has dealt with such practises in relation to particular goods in earlier reports (Clause 15).

Some new sanctions are provided, in addition to those, such as price control, that Ministers already possess (Clause 13). "Competent authorities" (that is to say, the Ministers responsible for different industries [Clause 20]) are given power to prohibit by Order the making or carrying out of agreements, and to prohibit boycotts, conditional sales, and preferential terms. These Orders must not interfere with patent rights. Orders so made must be laid in draft before Parliament and approved by resolution of each House (a far shorter procedure than an act of Parliament). They can only be made if, on a reference not confined to the facts, the Commission has reported that the conditions to which the act applies prevail, and *either* the Commission has reported them against the public interest, *or* the House of Commons by resolution so decides (Clause 10).

No criminal proceedings can be brought under the act, but either the Crown or any person affected may bring civil proceedings for an injunction to stop the action prohibited or for any other appropriate relief. The Trades Disputes

Act of 1906 is not to apply to such proceedings (Clause 11). (This act prohibits any actions of tort against a trade union; and the term trade union in law includes many associations between master and master).

These are the main provisions of the new act. It is at once apparent that it is not a drastic measure. Although some new sanctions are provided for "dealing with mischiefs" (to take the words of the long title) and some hints have been given that existing powers, for instance of price control, may be used to control monopolies, greater emphasis, both in the act itself and in the debates while it was discussed in the House of Commons, was laid on "inquiry," and on the publicity which will follow it.

The philosophy behind the act is still that expressed in the White Paper on Employment Policy published in the spring of 1945 by the coalition government:¹ "... agreements ... to control prices and output, to divide markets and to fix conditions of sale ... or combines do not necessarily operate against the public interest, but the power to do so is there." In addition, it is held that insufficient information exists on the operation of monopolies and restrictive practices, and that only a detailed examination of each can bring out whether or not it works against the public interest. This for the present; but later, as the Commission develops experience, the government (though not the Opposition) holds that it can usefully pronounce on the merits or demerits of particular types of restrictive practise, as a guide to business and the public.

The task before the Commission is a formidable one. First, it must interpret the public interest. It has, to guide it, the definition introduced into the Bill at third reading:

... all matters which appear in the particular circumstances to be relevant shall be taken into account and, amongst other things, regard shall be had to the need, consistently with the general economic position of the United Kingdom, to achieve:

(a) the production, treatment and distribution by the most efficient and economical means of goods of such types and qualities, in such volume and at such prices as will best meet the requirements of home and overseas markets;

(b) the organisation of industry and trade in such a way that their efficiency is progressively increased and new enterprise is encouraged;

(c) the fullest use and best distribution of men, materials and industrial capacity in the United Kingdom; and

(d) the development of technical improvements and the expansion of existing markets and the opening up of new markets.

All this is admirable. But it does not get the Commission very far. How is it to decide, for instance, whether or not to approve restrictive practises designed to maintain some rate of return on capital in a declining industry which, under competition, would work with no margin over prime costs? Prices above prime costs but below total costs could not be regarded as extortionate; but the capital already invested in the industry would be more fully used if prices were kept down. Again, when, if at all, should it

¹ Cmd. 6527.

permit the division of markets? Economists may think they know the answer to these questions. But not all economists would agree on all of them. And certainly economists would often disagree with businessmen or accountants.

The sort of difference of opinion that may arise is illustrated by two recent reports of committees of enquiry. One dealt with cement, the other with building materials and components generally. Both examined the system of fixed minimum prices and of deferred rebates to merchants which are forfeited if the merchant deals with any manufacturers outside the agreement. The first committee found that the price system as a whole was not an unsound one and that there was "sufficient bargaining power between the manufacturers and those interested in the rebates to make it right to leave these matters for adjustment between the interested parties."² The second found these practices to be "not in the national interest" and regarded it as essential that they should be eliminated.³ (It should perhaps be added that there was an economist on the second committee but not on the first.)

It is not, of course, true to say that the Commission will be left quite as unassisted in interpreting the public interest as were the various prewar bodies set up to supervise or comment on the actions of different statutory monopolies. It is told that production should be "by the most efficient and economical means" and that organisation must be such that "efficiency is progressively increased and new enterprise is encouraged." Presumably this should rule out the exclusion of newcomers and the organisation of restriction schemes which, like the Rubber Restriction Scheme in Malaya, benefited the high-cost producers (the plantation producers) at the expense of the low-cost native producers.

Both the government and the opposition realised the difficulty and the importance of the task entrusted to the Commission. The President of the Board of Trade said that he was determined to seek good members of the Commission. Some might be full time but others would be part time, persons already holding responsible positions which they did not wish to give up.

The task of interpreting public interest is thus left mainly to the Commission. But not wholly. As stated earlier, the act permits the House of Commons by resolution to decide that actions taken are against the public interest even though the Commission has decided otherwise. This clause was strongly opposed by the opposition, on the grounds, mainly, that it introduced politics unnecessarily, and that the Commission's findings should only be over-ruled by an act of Parliament, involving several full debates in Parliament. The decisions involved are major decisions, and controversial ones; it is difficult to see how, in the absence of a statement in the act of what type of monopolistic practices should be regarded as against the public interest, the matter can be wholly left to the Commission. And it is difficult to find time in Parliament for new Bills and several debates.

The task is formidable for a second reason, the number of cases to be

² *Cement Costs—Report by the Committee appointed by the Minister of Works.* H.M.S.O. 1947, pp. 21 and 22.

³ *The Distribution of Building Materials and Components. Report of the Committee of Enquiry, appointed by the Minister of Works.* H.M.S.O. 1948, pp. 21-26.

surveyed. Monopoly and restrictive practises in the sense defined by the act are very numerous indeed in British industry. Under the act, it is clear, progress in examining them all will be very slow. And it is far from clear that the sanctions provided in the act or by other legislation will always be adequate to ensure that actions decided by the Commission or the House of Commons to be against the public interest will be prevented in future. Monopolistic agreements can be terminated or forbidden, and boycotts, conditional sales and preferential terms prohibited. This may be adequate for the cartel type of monopoly, where firms maintain their separate identities. But it only touches the fringe of the problem presented by dominating firms or trusts. These fix their own prices and output, and can do so in a monopolistic fashion without any agreement. For these there remains, perhaps, the sanction of price control. But it is precisely in dealing with monopolies of this sort that price control (never a very effective sanction) becomes most ineffectual. Such control must be based in some way on costs; and the only costs available to be measured are those of the dominating firm. Either the firm is encouraged to keep up its costs, and thus the imposed price; or it is allowed to retain part or all of any profits resulting from lower costs, and the control gradually becomes inoperative.

Reliance has therefore to be placed on publicity, and on a change in the attitude of industrialists towards monopoly as the Commission pronounces on individual cases and gives a lead on policy. It is here that must lie the greatest hope of speedy action. The Commission cannot itself examine many cases a year. But if its decisions on one case influence the actions of a large number of businesses not themselves examined, it may affect many monopolies.

The Commission will have plenty of work within the framework of the act. None the less, it is perhaps unfortunate that cases of monopoly expressly authorised by law may not be referred to it. These fall into two broad groups, the nationalised industries, which have absorbed many of the large public utility monopolies, and agreements among privately owned firms authorised by statute. The opposition strongly urged that nationalised industries should be subject to an "efficiency audit" by the Commission. But this is a different task from that of seeing that the desire for private profit does not damage the public interest. It therefore seems reasonable not to place this considerable extra burden on the Commission.

On the other hand, privately owned firms or industries which are placed by law in a monopoly position present many of the same sorts of problems as other privately owned monopolies. The expertise which the Commission acquires in studying the latter should be useful in dealing with the former. Probably the most important of this type of monopoly before the war were the Agricultural Marketing Boards. At present most of their prewar functions are exercised by the Ministry of Food. The government is to produce a Bill about their future. If they are to be perpetuated, it may be hoped that their activities will be subject to investigation by the Commission rather than by the somewhat ineffectual and powerless Committees which had this task before the war.

COMMUNICATIONS

The Foreign-Trade Multiplier, The Propensity to Import and Balance-of-Payments Equilibrium

What may be a formal error in an article of mine¹ has come in for attack in literature in international economics which has belatedly come to my attention.² The present communication is designed to make confession to deviationism, if not to error in a formal sense; to enter a defense that the position taken conforms to the real world if not to the mechanics of the most popular economic models; and to suggest that neither my critics nor I have probed deeply enough into the subject.

The "error" appears in a discussion of the equilibrating mechanism in the balance of payments of a country with a high foreign-trade multiplier and a high propensity to import *vis-à-vis* a country with a low foreign-trade multiplier and a low propensity to import. A large increase in exports of the former was postulated. It was pointed out that incomes would rise substantially and that this would produce effects in turn on imports. The sentence which attracted the unfavorable attention started with the words: "This rise in imports may be larger than the increase in exports which prompted it. . . ."

The general law laid down by Samuelson, which he asserts is overlooked by many economic writers, reads: "So long as some fraction of income at every stage is leaking into domestic savings, a new dollar of exports will never be able to lift income by enough to call forth a full dollar of new imports."³

¹ "International Monetary Stabilization," in S. E. Harris, ed., *Postwar Economic Problems* (New York, McGraw-Hill, 1943), pp. 375 *et seq.*

² My "defective argument" is attacked explicitly in S. Enke and V. Salera, *International Economics* (New York, Prentice-Hall, 1947), Chap. 31, esp. pp. 599 to 606. It may be noted that the authors expressed their gratitude to A. I. Bloomfield for the basic ideas involved in their discussion. Bloomfield has been kind enough to show me the typescript of his forthcoming *Capital Imports and the Balance of Payments, 1934-39*, which contains a substantial footnote in Chapter 9 devoted to the demolition of my argument.

It has been suggested to me, moreover, that I represent the "many economic writers" who have overlooked the general rule set forth by P. A. Samuelson in his *Economics* (New York, McGraw-Hill, 1948), p. 392. L. A. Metzler, who charged me with error verbally upon the appearance of the article when neither of us had sufficient leisure to discuss it, may also have had the point in mind in making his contrary positive statement in "The Theory of International Trade," in H. S. Ellis, ed., *A Survey of Contemporary Economics* (Philadelphia, Blakiston, 1948), p. 215.

In addition to the foregoing, it was a common occurrence during the portion of the war I spent in Washington to be stopped on the street by fellow economists and to be told that my argument had been demolished by their graduate students.

³ That this is not an entirely accurate way of stating the point is understandable in an elementary textbook. What Samuelson means, of course, is, "So long as some fraction of income at every stage is leaking into savings and *no induced increase in home investment*

Enke and Salera list the foregoing among the reasons which prevent an increase in exports from calling forth a larger increase in imports and clinch their case by adding that "there is scarcely any case where the marginal propensity to save is not a positive quantity."⁴

The deviationism to which I am prepared to confess consists in the fact that I was talking not about the economic models discussed by Machlup in his *International Trade and the National Income Multiplier*⁵ but about the behavior of real economies. In Machlup's models, for example, the increase in exports (or other primary disbursements) must be sustained. "This technique does not deal with the effects of a single dose. . . ."⁶ It is also assumed that home investment is entirely unaffected by the changes in foreign trade as well as by the changes in income which may result from foreign trade.⁷ Nurkse chafes at the restraint imposed by this assumption.⁸ But given his assumptions, Machlup's models and his discussion of what the multiplier will and will not do are of high pedagogic value. Machlup admits that ". . . objections may indeed discredit the theory insofar as its application to concrete situations is concerned."⁹

The case I had in mind in suggesting that the combination of a high foreign trade multiplier and a high propensity to import might overcompensate for a favorable balance of payments was the Argentine example of 1936-38. In the fall of 1936, the failure of the American corn crop and a tight grain position in Europe called forth large corn exports from Argentina at good prices. Income in Argentina rose. The Argentine central-bank authorities attempted to use the afflux of foreign exchange to repay foreign debt owed in New York and shortly to become due. The inexorable rise in imports, subsiding only slowly long after the export position had returned to the *status quo ante* (and had even deteriorated) eventually required the Argentine authorities to enter into new loans in the New York market.¹⁰

Arthur Smithies has suggested to me that the Australian economy tends to behave in the same way that the Argentine economy did during this period; increases in exports generate surpluses in the current account which subsequently give way to deficits. cursory examination of merchandise-trade

occurs, or so long as the volume of income leaking into savings exceeds induced increases in home investment, a new dollar of exports, etc."

⁴ *Op. cit.*, p. 601.

⁵ Philadelphia, Blakiston, 1943, *passim*.

⁶ *Ibid.*, p. 7.

⁷ *Ibid.*, p. 19.

⁸ In his "Domestic and International Equilibrium" in *The New Economics*, S. E. Harris, ed. (New York, Knopf, 1938), p. 267. It may be noted that Nurkse and Metzler both postulate the possibility that the action of the foreign-trade multiplier and the propensity to import may use up the foreign-exchange surplus initially created by the autonomous increase in exports. They, therefore, either belong to the group of writers which have overlooked the general law enunciated by Samuelson or disagree with Bloomfield and Salera as to the possibilities of the propensity to save being zero.

⁹ *Op. cit.*, p. 9.

¹⁰ The position can be illustrated concisely by the following figures from the League of Nations, *Balance of Payments, 1938*:

figures for the same period as in the Argentine case suggests a closely parallel behavior. Imports in this instance failed to turn downward in the same year as exports.¹¹

It might be argued that the figures showed simply the effects of alternate rising prosperity and depression in the United States as effected through the 1936-37 inventory boom and the subsequent slump. The reaction of changes in exports on imports through income would then be so slow or incomplete¹² as to produce balance-of-payments surpluses abroad in times of American prosperity and deficits in depression. I do not think so, though the evidence is worth more detailed investigation. In the Australian case, imports continued to rise after exports had turned down moderately. In the Argentine, imports of machinery continued to rise in 1938 after exports had fallen drastically. In my judgment, negative savings within the countries (or in-

ARGENTINE BALANCE OF PAYMENTS IN CURRENT ACCOUNT (LESS GOLD)
(in millions of pesos)

	<i>Credits</i>	<i>Debits</i>	<i>Balance</i>
1935	1774	1760	+14
1936	1900	1783	+117
1937	2531	2213	+317
1938	1540	2051	-511

Further investigation into the detailed figures on a monthly basis might be rewarding. A chart in League of Nations, *Review of World Trade*, 1938, p. 26, shows that the increase in exports was concentrated in the last half of 1936 and first half of 1937, and that imports were much higher in relation to exports after mid-1937 than before. The *Review* further points out that imports of machinery into the Argentine, which had been two-thirds higher in 1937 than in 1946, rose by another 31 per cent in 1938. This suggests that home investment was taking place on an increasing scale.

¹¹ From the *Review of World Trade*, 1938. Balance-of-payments figures comparable to those used for Argentina are not readily available in the League of Nations material for 1938. Debits, moreover, contain a large and sluggish item of interests and dividends.

AUSTRALIAN MERCHANDISE TRADE
(in millions of old gold dollars)

	<i>Exports</i>	<i>Imports</i>	<i>Balance</i>
1935	264.7	226.4	+37.3
1936	301.9	256.2	+45.7
1937	347.9	296.8	+50.1
1938	306.0	305.0	+1.0

With a merchandise-trade surplus of only \$1.0 millions old gold dollars, the total Australian current account was sharply deficitary. Indeed, the account was in deficit in all four years above.

¹² See Metzler, *op. cit.*, pp. 219-20, who states: "While some difference of opinion still exists concerning the role of induced investment, the conclusion of most economists seems to be that, except under unusual conditions, the adjustment of a country's balance of payments by means of income movements is likely to be incomplete."

I would agree that conclusions must be tentative (as indeed was my original statement). I am inclined to think, however, that in the present stage of economic development of a number of countries in the world, the operation of the foreign-trade multiplier (*cum* induced home investment) and the propensity to import may tend to produce an incomplete adjustment to decreases in exports and an overcomplete adjustment to increases.

duced investment) prolonged the adjustment to the rise in exports. I would not, however, expect a ready and complete adjustment to a decline in exports. I fail to find it strange that the savings function of a country may be negative under certain dynamic conditions. It is true that, in general, individuals tend to save more as incomes increase. But at certain stages in rising standards of living, both secularly and during the cycle, savings in certain income groups may become negative as individuals go into debt to purchase durable goods pertaining to a higher standard of living. Such action can take place in response to an increase in income. Growing companies may expand their borrowing at certain points in their history in response to an increase in net revenue. Similarly, it may be that countries, whether deliberately in planned fashion, or through the agglomeration of thousands of individual decisions, may live above their means for a time in response to an increase in income. This type of response, when capital is not available for borrowing from abroad, may lead to a severe loss of reserves of gold and foreign exchange.

The Bloomfield-Enke and Salera argument that this thesis cannot be true because its converse cannot be demonstrated is based on novel if fallacious logic. I would answer that it is possible to regard the demand for commodities in international trade as elastic with respect to increases in incomes and inelastic with respect to decreases. This proposition is familiar enough in this country, where luxuries have a habit of becoming necessities. *Ab initio*, of course, a decline in exports cannot produce a drastic decline in income and commodities for which the demand is elastic if imports of the latter at this standard of living are small. An increase in exports, on the other hand, could produce a large increase in these classes of imports.

While I must insist on the validity of the point as made in my original article, I am prepared to negotiate on a generous basis with any critic who chooses to contend that its importance was exaggerated.

C. P. KINDLEBERGER*

Central Banks and the State: A Comment

In a recent issue of the *Review*, Mr. Kriz traces, with extensive and useful documentation, the increasing subordination of central banks to Treasuries.¹ With full recognition of Mr. Kriz's material contribution, he fails to bring out what may be the most important aspect of this continuous reduction in the independence of central banks.

A generation ago, the quantity of money was widely believed to be related precisely and immediately to the price level. This influence on the price level, of course, was viewed as one of the leading factors in maintaining the general economic health of the economy. There were, to be sure, many dissenters from this extreme view but in the area of public policy formation it was dominant. Thus, when central banks inherited, assumed, or were assigned

¹ M. A. Kriz, "Central Banks and the State Today," *Am. Econ. Rev.*, Vol. XXXVIII, No. 4 (Sept., 1948), pp. 565-80.

monetary powers, this prestige was bound to be great. And because of the vast importance attached to these powers, it was felt that central banks should be insulated from the more direct impact of current politics to safeguard the exercise of these monetary powers.

But the more dogmatic quantity-of-money views have lost their standing. While it would be wrong to say that fiscal policy has displaced monetary policy in professional and popular regard, there has undeniably been a large shift in this direction. Certainly small monetary actions and moderate changes in the quantity of money are no longer regarded as important as they once were. On the other hand, small fiscal operations, quarterly tax payment dates, for example, have been given increasing attention in the analysis of current economic conditions. But in the administrative branch of government, fiscal matters have always been in the province of the Treasury. Thus, with no change in the distribution of formal powers, the change in the evaluation of powers demoted central banks relatively and at the same time raised the prestige of Treasuries.

In these circumstances, it is fairly obvious (and clearly true in practice) that when there tends to be a conflict of monetary and fiscal considerations, the fiscal ones take priority, the monetary ones give way.

It was not just the growth of public debt or its absolute size that accounted for greater importance of Treasuries; it was that public debt management came to have more aspects of monetary management. It was through the channel of public debt that Treasuries came to have a much greater voice in monetary matters. Fiscal effects do not end with the determination of the size of the public debt; the matter of how the debt is financed is of almost equal importance. When public debt is financed through the banking system, the results are relatively inflationary (to the extent there is any residual truth in quantity-of-money influences). Financing by sale of public debt obligations to the non-banking public is as such deflationary, and might undo some of the expansionary effect of the deficit spending.

Mr. Kriz is right in averring that the decline of the international gold standard was one of the leading factors shifting the balance of authority between central banks and Treasuries. As long as the gold standard prevailed (and more important as long as the logic of automaticity that it implied was accepted by the financial community), the action of the central bank in protecting its own gold reserves was identified with the public interest. But when faith in automaticity was shaken and when the international gold standard was no longer general, central banks were without the tools or the logic for international monetary action. Their future actions are most likely to put domestic considerations ahead of international ones, except in case of war. An action such as the increase in discount rates in the midst of a deep depression by the Federal Reserve System in September, 1931 when England departed from the gold standard, a case of putting gold standard considerations ahead of domestic economic needs, probably will never take place again.

But Mr. Kriz could have made this international point even more emphatic. The nature of international relations has itself changed. The ends of international economic policy are now seldom economic ones; they are more often

political or even military. When the governments of powerful nations are scrambling in the world arena for position and prestige, it becomes unthinkable that the central banks of any one of them should stand out against their governments. It is not so much that central banks have, in this connection at least, lost place *vis-à-vis* Treasuries; but rather that both have been forced to look less to economic ends in matters of international policy and more to other factors.

In any event, once the logic of automaticity in monetary policy is lost and the ideas of monetary management creep in, it is unthinkable that the agency exercising the powers of monetary management would be independent of government. In fact, the political independence of central banks was mainly a goal of those who hoped either by adherence to the domestic gold standard or by inviolate legislative rules to make money supply a function of rule and not of administrative authority. The question of whether the administrative authority was the central bank or the Treasury was far less important.

One final exception may be taken to Mr. Kriz. He lists the Federal Reserve banks as owned by the "private" member banks. Strictly speaking, he is right but to direct attention to this aspect of Federal Reserve organization is to misconstrue the facts. The balance of major authority in the System proves it to be a "public" agency.

Particularly since the Banking Act of 1935, the balance of power within the System has been clearly on the side of the central organ of the system: the Board of Governors. This Board is clearly an agency of the federal government. Its membership is appointed by the President with the advice and consent of the Senate. Although the Board has avoided partisanship in the narrower sense, it is clearly "political" in the better sense of the word. The chairman of the Board serves a four-year term, but in practice though not in law, he continues to serve only at the pleasure of the President. The prestige of this position is such that the current political administration cannot help but have an overwhelming influence on the Board. Nor is this meant to sound bad; an administration could not discharge its economic functions without control of monetary powers.

Between the Board of Governors and the Federal Reserve Banks, the balance of authority has been considerably shifted toward the Board during the past decade and a half. The seven members of the Board are a majority of the powerful Open Market Committee. The Board itself sets the reserve requirements of member banks (within the margins permitted by law), and it in effect controls bank discount rates. Without minimizing the advisory influence of the Reserve banks, their direct role has been a shrinking one.

What is probably more important, the Reserve banks themselves have become conscious of their public position and their acts and utterances have taken on a quality of public statesmanship which was not true of earlier years. They represent an admirable blend of public and private characteristics reminiscent of the traditional Bank of England position.

BOOK REVIEWS

Economic Theory; General Economics

Towards a Dynamic Economics. By R. F. HARROD. (London: Macmillan & Co. 1948. Pp. ix, 169. \$2.25.)

This is an important and penetrating book. The fundamental ideas are based on Mr. Harrod's brilliant article in the March, 1939 issue of the *Economic Journal*. Here the analysis is presented more fully, and there is considerable new material dealing with the supply of saving, the foreign balance, contra-cyclical policy, and interest-rate policy.

The volume as a whole centers around the problems of a *growing* economy, in particular those associated with the process of saving and capital formation. Those who are concerned with problems (like those confronting the Council of Economic Advisers) relating to stability and balance in the nation's *economic* budget will find highly stimulating suggestions for empirical research, particularly in the area of maintainable rates of growth of the capital stock.

In the author's view, the definition of dynamic economics as that branch of theory in which every quantity must be dated (Hicks) may indeed be a genuine mark of the study of oscillation in terms of time lags. Nevertheless, for Harrod, dynamics has to do with "continuing changes generated by the special nature of a growing economy" (p. 11). Dynamics is concerned specifically with the effects of continuing changes and with rates of change (p. 8). The trend of growth may itself generate forces making for oscillation. The study of rates of growth and time lags should indeed go together, but dynamics is mainly concerned with growth and continuing rates of change.

Thus Harrod goes back to the classicals prior to Marshall. The "classical economics contains in roughly equal proportions what I define as static and dynamic elements" (p. 15). Saving is rightly treated by Ricardo as a dynamic concept. So long as there is any positive saving, the shape of society is progressively altering (p. 16). Dynamics is concerned with growth. In a dynamic system the quantity of resources devoted to production is steadily growing. Dynamics must concern itself with "the necessary relations between the rates of growth of the different elements in a growing economy" (p. 19).

Growth of the capital stock depends upon: (a) population growth, and (b) technological advances (productivity per head).¹ Growth of the capital stock, commensurate with growth in the labor force and technological ad-

¹We may usefully divide capital growth, I would suggest, into two categories: (a) widening of capital, and (b) deepening of capital (meaning more capital per worker, *not* more capital per unit of output as with Hawtrey). "Widening" of capital means in these terms simply equipping the net additions to the labor force with standard capital equipment. This requires no change in technique, only a growth of population. "Deepening" of capital means to equip each worker with more capital. This requires a change in technique, if we assume the rate of interest constant.

vances, will raise output (real income). The ratio of capital to income is the "capital coefficient." Inventions, while usually increasing the capital per worker, *may* leave the capital coefficient unchanged.²

The heart of the book may be found in Chapter III on "Fundamental Dynamic Theorems." The equations presented deal with the basic problem of the capital requirements of a growing society, the propensity to save, and the rates of maintainable growth. A "higher propensity to save does, in fact, *warrant* a higher rate of growth. Trouble arises if the rate of growth which it warrants is greater than that which the increase of population and the increase of technical capacity render permanently possible" (*Economic Journal*, March, 1939, p. 31). The *normal* rate of increase is that determined by the fundamental conditions of a steadily advancing economy enjoying given trends of population growth and technological advances.

Here we encounter the fundamental equilibrium equation, $G_w C_r = s$, in which G_w expresses the rate of "warranted" growth in an economy with a given propensity to save, C_r is the new capital required to sustain a given increment of output, and s is the fraction of income which individuals and corporations choose to save.

But now G_w may have no relation to "the rate of advances which the increase of population and technological improvements allow (p. 87). This latter, designated G_n , may be called that *natural* rate of growth of output associated with the growth of capital required by population increase and technical advances. Now the basic capital requirements ($G_n C_r$) may not correspond to the propensity to save. Quite possibly $G_n C_r \neq s$. It is the divergence of $G_w C_r$ from $G_n C_r$ which presents the problem of chronic unemployment.

Mr. Harrod considers another equation, a truistic one representing *ex post* the actual fluctuations in rates of growth in output, G ; actual fluctuations in the rates (marginally considered) of capital to output, C ; and finally the per cent of income saved, s . Thus the equation $GC = s$ is simply an identity statement reflecting *actual* changes in these variables. The problem of the trade cycle relates to the divergence of the *actual* rates of growth G , from G_w and G_n .

If G exceeds G_w , as it is likely to in a high boom, capital formation will exceed savings at full employment and inflation will result. If G falls below G_n , then capital formation will fall below the *normal* rate of growth, and so a backlog of investment opportunities will develop preparing the way for recovery.

Harrod's analysis is concerned on the one side with the problem of maintainable rates of investment, and on the other side with the problem whether autonomous investment impulses are sufficiently powerful to raise income enough to induce a full "widening" of capital. For example, in 1937-40, it

² Fellner (*Monetary Policies and Full Development* [1946], p. 80) gives capital coefficients for each of the five decades from 1884 to 1933 as follows: 2.8, 3.1, 3.2, 3.2, and 3.0. Using his data one can calculate for the same period the marginal coefficient (the ratio of the *increase* of capital to the *increase* of income from decade to decade. The marginal coefficients are: 3.9, 3.3, 3.1, and 2.6.

is quite clear that a government program to raise income to a full-employment level could have *induced* considerable capital formation, thereby bringing capital facilities (steel, for example) up to the level of the requirements of a full-employment income.

Mr. Harrod explicitly states in the foreword that Britain can look forward to a considerable period in which the interwar difficulties due to over-saving will not recur. But he nonetheless believes that "sooner or later we shall be faced once more with the problem of stagnation; and that it is to this problem that economists should devote their main attention." Moreover, he suggests that "the United States is not likely to be exempt from the problem of chronic depression," and so he deems his analysis to be of "urgent and vital relevance" here.

The main solution offered by Mr. Harrod for the long-run problem, as distinct from that of the cycle, is to drive down the rate of interest. A fall in the rate of interest would tend to raise the capital coefficient C_r , thereby helping to bring $G_r C_r$ into balance with saving. Yet he admits that even a zero rate of interest might not produce enough effect on investment (*via* the increase of capital in relation to output) and on saving to secure steady progress.

To the reviewer, a serious limitation of the proposal is the fact that any capital formation induced by a lowering of the rate of interest is a once-over push; once the capital stock has been built up to the level indicated by the low interest rate, investment outlets are again limited to the growth requirements of population increase and technical progress. Thus no *continuing* solution can be found *via* the interest rate. A low rate of interest might of course (the pros and cons of which would require another essay) be defended on other grounds.

Finally, the particular devices by which Mr. Harrod hopes to achieve his results are broadly similar to those proposed by Professor Frank Graham in *Planning and Paying for Full Employment*. For a critique of these ideas see my *Economic Policy and Full Employment*, Chapter XVIII.

What is really important in this book is not the practical policy sections, but rather the theoretical apparatus outlined for a study of dynamic economics. Mr. Harrod has given us an elegant piece of analysis, highly original, and pregnant with suggestions for theorists, econometricians and students of the business cycle.

ALVIN H. HANSEN

Harvard University

Income, Employment and Public Policy: Essays in Honor of Alvin H. Hansen.
(New York: W. W. NORTON. 1948. Pp. viii, 379. \$4.00.)

In this volume, sixteen former students or close associates of Professor Hansen have contributed essays generally germane to his work; most of them being expressive of American Keynesianism, theoretical or applied. They have been grouped into three parts, headed: "Determinants of Income" (meaning total national income), "Social Setting" and "Economic Policy." The essays in Part I generally treat the economy as a mathematically analysis-

able mechanism, though on that score, Robert L. Bishop's diagrammatic analysis of the three expansionist fiscal policies, which is placed in Part III, could as well be placed in Part I. The three essays in Part II are presumably placed there because they are broader in range or perspective than the others—in three quite different ways. In the seven essays which make up Part III, "economic policy" is dominated by fiscal policy, taxation and the national debt; the only exceptions being Alice Bourneuf's specialist's account of "Exchange Practices and the Fund" and John Dunlop's notable essay on wage-theory. Judging from the internal evidence, the essays were not written to fit into a table of contents, and the degree of unity they show is evidence of the trend of their authors' thinking, rather than of editorial planning. The anonymous editor's task of grouping and classifying them was both necessary and difficult.

The reviewer, naturally, cannot discuss adequately each of sixteen essays; nor can he discuss them as a group without doing injustice to the extent to which each is an individual product. In general and prevailing, the reader finds the economy treated as a massive and impersonal mechanism, with consumption an unvarying function of an individual's disposable income, and with a less unanimous tendency to take private investment as given, or to pay scant attention to the questions of motivation, and especially the more imponderable motivations, that underlie the behavior of private investment. There is also a tendency to slight the real problems of inflation by assuming that it is something that arises only when income exceeds the full-employment level, and that inflation and depression are simple opposites (Bishop, p. 318). This is perhaps part of a general tendency to neglect problems of the wage-price structure. The exceptions to these tendencies acquire scarcity value.

One of these is David McCord Wright's essay on the effects of income-redistribution. This stands out as a liberal document, concerned with qualitative matters and with the reactions of flesh-and-blood individuals. He stands for a balanced system, permitting some equalization of incomes, and stressing the importance of preventing severe deflation; but his emphasis is on the danger of going too far, in too doctrinaire a spirit.

"An uncritical acceptance of literal equality of income as a positive goal, and a preference for state action upon all occasions, will leave the regime of 'guided capitalism' devoid of vitality, or excuse, and ripe for extinction." This would mean economic stagnation, through the "law of deterioration of self-perpetuating groups," and the crushing of political democracy, because the dissenter will have no chance against the economic power of the monolithic employer. Compared to this, the kind of competitive forces that can still be preserved, imperfect as they are, seem to him vastly important. His program centers on the attempt to strengthen them, and in that light the main positive argument against drastically progressive taxation seems to be that it prevents the small concern from growing large by plowing back its earnings, and tends relatively to strengthen the position of the interests that have already arrived; and to prevent the group of leading concerns from growing as numerous as would be desirable.

Negatively, he combats the argument for complete equality of income which is based on diminishing utility. He emphasises the capacity of conscious wants to adjust themselves to income, and adds that the actual consumption of the rich is a relatively small matter in the national total. I believe I am representing his argument correctly in adding that in ethical terms which are the important ones in this case, inequality of income is rather incidental to tendencies of our time which "go far beyond mere capitalism." He holds that progress, both in the larger matters and in the ethical quality of the competitive game, hinges on the influence (without coercive power) of an elite who have influence and the will to use it, but are also willing to learn. This he admits represents a delicate balance; and it seems to be implied that, when it should come to the balance involved in deciding how far progressive taxation should go, one very important consideration would be its effect on the standing and morale of this elite class.

Who are they? Wright uses the term "intelligentsia" to describe them, but they are apparently not coextensive with the "cultural elite," whose present prevailing attitude seems to be precisely what Wright deplors. They are justifiably alarmed about conditions, but alarm takes a misguided direction. "In the end, I believe, the intellectuals who destroy business competition in the name of redistribution, security and planning, because they hate Main Street, will find that they have destroyed the very diffusion of power which protected them from Main Street." In terms of what the reviewer has called "strategic decisions," Wright gives the maintenance of a strong competitive system priority over any very exacting degree of "full employment" or of equalitarianism. What this would seem to mean is to limit employment policy to what can be done by fiscal and monetary means, with the faith that this can keep recessions within bounds that can and will be tolerated. And the obvious question is what would happen to this strategic decision if, in some recession, unemployment should rise, let us say, to eight or ten per cent of the working population.

Turning to Dunlop's essay, he takes as his point of departure Hansen's theory of economically sound wages, consistent with a stable price level and therefore rising, on the average, only as fast as average productivity rises in the economy at large; but with wages in particular industries following a compromise course between the average rate and the varying rates of increase of productivity in the different industries. To this, Dunlop contributes an enlightening analysis of the extent and causes of departures from a balanced wage structure, defined as similar rates of pay for services that are similar in terms of skill, experience, training and other such factors.

He finds a strong tendency to this kind of balance within the area of a bargaining unit, which is in some cases narrower than an industry and in some cases broader. Departures are due, among other things, to differences in rates of increase of productivity or of demand (the two being interrelated). These factors have more effect under piece-work, or if wage-leadership is located in rapidly advancing industries, and less effect where one bargaining unit covers more than one industry, or where strong price competition gives most of

gain to customers, leaving little excess profit for wages to tap. Wages also tend to rise more where they constitute a small part of total cost, and where skill and similar requirements have risen. Rates of wage-change vary widely from industry to industry (the showing of bituminous coal would have changed spectacularly if the figures had been carried down to date instead of stopping at 1940). Dunlop accepts this wide dispersion as refuting the idea that rates *should* stay close to the average; and it seems at least to cast doubt on the *practicability* of attempts to stick very rigorously to previous differentials. But he indicates that the factors listed tend to set limits on dispersion.

The reviewer suspects that this is an example of a type of development that is needed to give relevance and realism to our whole traditional theoretical structure, from marginal utility or indifference curves down, substituting a zone of indeterminateness for a sharp line, and complementing this with active investigation of the forces that set limits on the width of the zone, and those that create variations within it. Taussig's "penumbra of supply and demand" was an early instance of the zone concept, but the second kind of study seems needed to complete it.

Another essay, not quite in the line of prevalent Keynesian emphasis, is E. C. Brown's examination of ways of taking the negative effect on investment incentives out of heavy business taxation. The analysis is technical, and the devices suggested may be too involved to be readily convincing, but the importance of the subject urges serious consideration of such proposals. It is refreshing to see this much attention given to the impact of fiscal policy on incentives to investment.

E. D. Domar also is concerned about private investment. He classifies it into spontaneous and induced, admitting some violence to logic, and not reckoning with the fact that actual investment is jointly affected by both kinds of causes. He is concerned about monopolistic obstructions, and gives a very lively and convincing account of the way desirable investment may be vetoed by existing interests in a hypothetical planning conference (p. 52). In so far as the loss from scrapping old investment is a deterrent to making new ones, he indicates that this deterrent varies with the percentage of the market the concern holds (p. 36), later concluding that "it is not monopoly in the narrow technical sense that matters, but rather bigness in general" (pp. 51-52). He has demoted to a footnote Kuznets' contention that large expected demand is a factor making replacements more economical, and indicating or at least implying that bigness has favorable as well as unfavorable effects.

As to induced investment, he holds it cannot happen so long as unused capacity exists (p. 46). This seems to leave out of account the theory and practice of stand-by capacity, which is the most economical way of handling short peaks, but is substandard for anything like continuous use, and may be replaced if demand improves to an extent creating an expectation that this stand-by capacity may be utilized, for example, 70 per cent of the time instead of 20 per cent. In such a case, "excess capacity" is a relative term; and the kind that is nearly always present does not veto induced replace-

ments. Later (pp. 46-47) Domar takes the extraordinary position that investment, increasing in response to increased income, does not count as "induced investment" until it exceeds the amount necessary to absorb voluntary savings, or to maintain "full employment." He seems to regard induced investment as desirable; yet investment beyond that point is inflationary, by definition. He estimates the critical rate of investment as increasing productive capacity 4 per cent per year; hence it requires 4 per cent increase of (real) income per year to bring it about. This is based on an estimate that marginal savings are 12-15 per cent of income (Duesenberry's formula gives not quite 10.23 per cent for the long-term trend); and that a dollar of added investment increases annual output-capacity by 25 to 33 cents. This gives a range of 3 to 5 per cent, or 2.56 to 3.41 per cent on Duesenberry's basis. If Duesenberry's figures are correct, Domar's 4 per cent would be mildly inflationary. He has rendered a service by undertaking a quantitative first approximation to the rate at which our Red Queen economy has to expand, to stay in the same place in terms of employment; but his 4 per cent is clearly a very rough estimate, and probably high.

James S. Duesenberry undertakes to bring under one formula the short-run and long-run savings functions, the rationale of his formula centering in the idea that the highest consumption previously attained tends to become imbedded in the standard of living, so that if income shrinks, consumption shrinks less than in proportion, and restores itself when income recovers, while the long-run trend is a constant proportion of income. His formula is:

$$\frac{S_t}{Y_t} = .165 \frac{Y_t}{Y_0} - .066 \text{ where } Y_t \text{ and } S_t \text{ are income and savings of any}$$

given year, and Y_0 equals the highest income of any previous year. This formula gives a higher marginal rate of savings for cyclical fluctuations than for secular trends, but has some tricky properties. With a steady increase of income at 2 per cent per year, a constant 10.23 per cent of income would be saved; and the secular trend through a series of cycles would be about the same. In a depression, the percentage of saving shrinks, reaching zero when income is 40 per cent of the previous high. At 20 per cent of the previous high, savings, having become a minus quantity, go no lower, and rise to zero as income goes to zero. The author notes that these peculiarities appear only outside the extreme range of probable fluctuation; but they cause the sensitive marginal rate of saving to change, even within the normal margin of fluctuations, starting at 26 per cent and diminishing as income shrinks below its previous high.

Duesenberry thinks in terms of a major cycle having an approximate ten-year term; and the percentage of income saved at the peak of such a cycle can vary between the extreme limits of 10 per cent and $13\frac{1}{2}$ per cent, according as income for the peak year exceeds that of the preceding year by a negligible amount, or by substantially the whole of the ten years' trend increase (which I am reckoning at 22 per cent). As a result, during a depression following a very sharp peak, the savings shown by the formula would be a little smaller, and consumption a little larger, than the rationale would call for. The formula, in effect, represents consumers as struggling to protect,

and to return to, a rate of consumption of 90 per cent of previous income, though their highest previous actual consumption (that of the peak year) may not have risen above 87 or 88 per cent. The formula registers the effect the previous peak income would have had on consumption if it had been sustained, when it may not have been sustained enough to have that effect. These peculiarities may not constitute major defects; but it is not clear that this formula is superior to the simpler procedure of reckoning marginal saving equal to average in the long-term trend, and perhaps twice as great, or more, in cyclical fluctuations. Goodwin's essay (mentioned below) contains a way of separating cyclical and trend marginals (p. 125).

L. A. Metzler traces three lags in the circular flow of income, which have been incorporated in simplified cyclical models and which appear to him to be the principal lags, or the principal ones accessible to measurement by present unrefined techniques. There is the lag of consumers' expenditures behind income payments (associated with D. H. Robertson), the lag of output behind change in volume of sales (associated with Eric Lundberg) and the lag of income payments behind changes in output. His principal conclusion is that the first lag is short, relative to the second.

Some other time-relations may be important, including those complicated by increase or decrease of inventories or fixed investment, which may disguise the lead-lag relationships. Timing of movements of costs and prices might also, it would seem, be significant.

So far, we have been considering essays that depart from typical 'neo-Keynesianism, either in basic perspective, or in introducing dynamic factors into the formulas (Keynes dealt with them outside) and undertaking to measure them. More in the orthodox line is Samuelson's essay on the mathematics of income determination. It exhibits what happens to the Keynesian theory when it is simplified by isolating the central mathematical formula and its corollaries from the context of factors that do not lend themselves to this treatment, and which Keynes handled in "literary" fashion. Samuelson starts by taking investment outright as a constant, with the result that the combined consumption-plus-investment function (in the now-familiar graphic exposition) intersects the income-line from above, creating a stable equilibrium. He then introduces an autonomous upward shift in the consumption function, by simply adding a factor a to the function as it stands. This serves to show that such an increase has a multiplier effect, just as much as increased investment does, but one wonders whether this simple mathematical device is adequate to all the possibilities of the problem.

More serious are the questions raised when "induced investment" is taken into account by making investment a rising function of income. Samuelson is still confident that this gives an intersection from above, giving a stable equilibrium. This must be conscious simplification, since his own earlier article on the synthesis of the acceleration principle and the multiplier includes explosive and oscillatory solutions. In the former, the intersection must be consistently from below; in the latter, intermittently so. To the reviewer, it seems that the relation of investment to incomes varies with time and past

changes of income, and therefore breaks down the whole static-equilibrium formula; which thus comes to constitute the chief error in the current simplified exposition of Keynesian theory.

In so far as investment responds to current income, its short-cycle response is, one would naturally assume, much more sensitive than its long-term trend response. But other factors enter in. The initial effect of a substantial increase in income, in a system which has either little unused capacity or many aging units, would be to increase investment demand so markedly that combined consumption-plus-investment would almost certainly intersect the income-line from below, destroying stable equilibrium and creating a cumulative upward movement. Is not this what regularly happens in the upswing of a cycle and in reverse direction on the downswing? The cumulative expansion cannot last indefinitely, for a number of reasons, not all of which seem amenable to treatment in this formula. For one thing, while money income might increase without limit, physical product is more restricted; and investment demand depends on physical product.

The upshot seems to be that investment cannot be treated as a simple rising function of current income alone, without doing violence to the essential facts; and that a more realistic (and dynamic) treatment inevitably introduces instability. Even without allowing for this, equilibrium comes to depend on the intersection of two lines which are so nearly parallel that the determinateness of the outcome becomes dubious (current graphic representations sometimes grossly exaggerate the angle of intersection). Samuelson saves himself by a concluding sentence, emphasizing "the violence done to complex reality by the simplified statistical abstractions of this paper." But is such a vague and general last-moment *caveat* sufficient?

He goes on to deal with more detailed problems, including the three methods of fiscal expansion, demonstrating that a dollar of increased public spending on a balanced budget increases income by exactly one dollar, and that this also applies to an increase of business investment, financed by an increase in business saving. He deals with the balance of corporate investment and saving, and with the balance of international payments; all in mathematical terms simple enough to be accessible to the non-specialist.

While Samuelson is oversimplifying his previous analyses, Richard M. Goodwin is developing them further, dealing with these matters of time-sequence, in highly mathematical fashion. He develops a "flexible form of accelerator," under which an increase in income gives rise to an increased equilibrium level for total capital, which capital would approach asymptotically (if income remained constant at its new level) with a diminishing rate of annual investment, always a constant fraction of the remaining difference between current total capital and its equilibrium level (p. 123). But this behavior of investment reacts on income, and this mutual reaction can produce an oscillatory model. Goodwin introduces constants which give nine-year cycles, each of half the amplitude of the preceding one, leaving outside disturbances to renew the oscillatory movement and keep it from dwindling to zero. As already noted, he derives independent marginal rates of consump-

tion for cyclical movements and long trends. He displays impressive resourcefulness in the mathematical handling of these dynamic relations; and leaves this reviewer behind before he gets to the point of grappling with irregular shifts in the "marginal efficiency of capital." If Goodwin's model is, as he recognizes, too mechanical to give results that conform fully to observation, the same must be true in much greater degree of Samuelson's and of simple graphic models like Bishop's diagrams of the three expansionary fiscal policies.

A. P. Lerner's essay on the burden of the national debt develops and defends the theme of "functional finance," explaining briefly the automatic check on inflation under this policy. Here he assumes that there is some level of total spending "high enough to prevent depression yet low enough to prevent inflation." He assumes that the tendency of a growing public debt to increase inequality of incomes can be offset by making added taxation more progressive; while the deterrent effects of heavy taxes on investment can be completely cancelled by full permission to offset losses against profits. Many must envy him his confidence on all these points. But a couple of pages later, he seems to have forgotten about unequal distribution, and is talking about a large debt making people in general so rich that "very little work will be done over and above that which is done for the pleasure of doing it"; at least when we get to the point where interest on the national debt is "many times as large as the income from other sources." We are warned, or promised, that we may be closer than we think to attaining this strange millennium. "In a rich country like the United States, if everybody had such an accumulation of government bonds that conspicuous consumption and display lost their significance, needs of material goods could be so simplified and reduced as to make their complete satisfaction feasible by the few hours' work that are necessary for health or may become necessary for social approbation." This combines the rather original fallacy that (unequally distributed) government bonds will make everybody so equally rich as to wipe out invidious consumption, with the older delusion that it is only this invidious element that prevents us from satiating our wants with a fraction of our present average consumption.

If this happens without heavy taxation, "nearly all goods will be free," only the taxation will be necessary to prevent inflation (by which these free goods would rise to exorbitant prices), only the taxation would be a worse evil than the inflation. And functional finance will prevent us from reaching this point, thus leaving the reader in additional doubt as to how seriously the discussion is meant to be taken. The reviewer cannot avoid the unworthy suspicion that Lerner has been using these imaginative flights to get the reader in a frame of mind in which the author's more serious views will look sound and sensible by comparison. If so, the effect on the present reviewer was the reverse.

Finally, Lerner argues that increased private debt is on all fours with increased public debt in the effects just discussed, sidestepping the fact that private investment creates salable goods directly and is financed out of the

prices charged, these prices taking the place of the taxation which Lerner argues would still be necessary to prevent inflation. Lerner's contention that "public investments may be just as useful in increasing future output" does not seem to meet the case. If they were useful *in the identical way*, they would not have the peculiar effects which Lerner had previously discussed. Once more, the reviewer confesses inability to take this argument seriously as an element in the pros and cons of functional finance.

In closing, Benjamin Higgins' discussion of secular stagnation may be mentioned. He gives a non-mathematical treatment, but rather handicaps it at the outset by a hypothetical diagram in which he compares the trend of gross national product at full employment and its actual trend, over a period of three Kondratieff or 17 Juglar cycles. The full-employment trend is a growth-curve, the "actual" trend is a less steep growth curve, starting above the former and ending below it, the intersection marking the beginning of "stagnation." This seems to be a basic error, because the actual trend strikes an average between cyclical troughs and peaks, and therefore is bound to fall below full employment, on account of cycles alone, even if there is no stagnation. So it seems that secular stagnation, if it comes, cannot be represented by any such simple device as the intersection of these two lines. By this device, the only condition that would *not* register as secular stagnation would be long-continued over-employment due to war or some other emergency.

In order to show an hypothetical period in which stagnation has not set in, Higgins starts his trend-line for actual employment fully 50 per cent above full employment! And the highest Juglar peak included in his first Kondratieff cycle is about 90 per cent above the full-employment trend! This appears to be a *reductio ad absurdum* of this diagrammatic notation, which is adapted to proving that any condition that could ever occur is one of secular stagnation.

At this point the reviewer wakes to the realization that he has given some individual mention to all but four of the sixteen essays. Feeling that the review must close, he presents his apologies to Messrs. Alexander, Musgrave, Perloff and Stettner. Despite a disquieting number of errors, it seems to the reviewer that Professor Hansen may well be gratified by the number and varied ability of the essays which are joined in this tribute. As a perspective of the present state of Neo-Keynesian economics, the volume shows a few useful deviations from what can fairly be called the orthodox Neo-Keynesian orientation and emphasis, and a larger number of useful dynamic developments and quantifications. The accompanying drawback is a tendency to be content with what can be done by mathematical formulas or diagrams, sometimes vastly oversimplified. Along with this goes a large amount of Keynesian discipleship that is more orthodox than the master. This was inevitable; and the tradition may outgrow it in time, if the constructive trends continue, of which this volume affords promising examples.

J. M. CLARK

Westport, Conn.

Democracy and Progress. By DAVID MCCORD WRIGHT. (New York: Macmillan. 1948. Pp. xvii, 220. \$3.50.)

Professor Wright has written the best defense of private enterprise we have seen. It is not a plea for *laissez faire* and the good old days—far from it—nor for the retention of capitalism “as is” without reconditioning. It is an argument, brilliant in many respects, for a flexible capitalism capable of adjustment to changing conditions.

Defense of private enterprise or any other system must be based on value-judgments. After ten years of reasonably “pure” economic analysis, Wright has concluded that “the man who wishes to avoid nonsense cannot study social policy on a technical level alone.” He has discovered that economic processes involve more than the price system, and that economic analysis cannot cope with the basic problems of economic life without attention to the sentiments which motivate it, as well as to the rational instrumental judgments which shape its policies.

He is fortunate in having made this discovery in so short a time—possibly as a result of his earlier training as a student of architecture. Many older economists have never made it, and many younger ones will not, so long as the present prestige of “objectivity” and mathematical analysis,¹ and our present narrow training of economists, persist.

Wright’s central thesis is the familiar one that all our liberties, including political democracy itself, depend on the preservation of the profit system, although he nowhere expresses the idea as baldly and naively as does most business propaganda. The competitive system, he says, is not in itself a guarantee of democracy and progress, but it is an overwhelmingly necessary condition for them. Capitalism is the only system we dare trust, and we would better not risk throwing the baby out with the bath by going in for comprehensive planning, swallowing Keynesianism whole, or uncritically accepting a New Dealish evaluation of security and equality.

Private enterprise, the argument runs, is the system demonstratedly the most favorable to scientific research and technological innovation, and therefore to material progress (bigger and better gadgets?); to alternative job opportunities for the worker—a condition given great emphasis as essential to economic and therefore to political liberty, and one which involves not only avoidance of government planning boards but also reform in trade union policies; and thence to “democratic opportunity” through the beneficent action of rivalry and competition (suitably divested of their more unlovely aspects). It is futile to suppose that planning and free enterprise are compatible, for comprehensive planning through authoritative government boards would reduce private business to an empty shell. It would put us under the thumb of a self-perpetuating bureaucracy, which, by its inevitable antipathy to technological change and innovation (since they would upset production and market forecasts and budgets) and its discouragement of risky investment, would result in a stagnant economy. Put in these general terms, the

¹ This is not to imply that these do not have their place. It is merely agreement with the author that by themselves they are not enough.

argument is familiar enough, and we might conclude that Wright only reiterates the stereotyped "line" of capitalist propaganda. Such inference would be mistaken, however, for his thinking is penetrating and independent, though his emphasis on invention and risky new ventures indicates the influence of Schumpeter. The book may well give pause to any but the most uncritical advocate of the Administrative State as well as to the equally uncritical disciples of Hayek and the invisible hand.

The last two-thirds of the book is devoted to a critical but somewhat sketchy consideration of well-recognized economic issues—instability, competition and monopoly, distribution of income, saving and investment, isolationism and tariff barriers, and the policies of organized labor. All through the analysis runs the case against comprehensive planning. On the other hand, the "friends" of private enterprise who oppose government regulation on principle are pointedly regarded as among its worst enemies. Wright shares the opinion of the more intelligent business leaders that the profit system must be made to work better than it has in the past, if it is to survive. It needs various readjustments. In refusing to scrap it for a streamlined experiment, Wright is aware that it is up to its defenders to show what can be done to make its performance reasonably acceptable, but he wisely refrains from offering a formal blueprint.

He contrasts two types of policy: the conservative, with its tolerance of private monopoly, its indiscriminate emphasis on government economy, and its high-tariff isolationism; the other, the "ultraliberal," a policy of "guided capitalism," which for brevity we may associate with the New Deal and the policies of the British Labor Party. He will not stand on either platform, but he takes some planks from the ultraliberals, while some of his ideas, particularly his opposition to progressive taxation, carry the odor of reaction.

The two main defects of capitalism are monopoly and instability. The aim of anti-trust policy should be the preservation of technological creativeness and economic democracy, the latter meaning fair competition and a chance for the little fellow. To this end, he advocates monetary policies to keep fluctuations within bounds, credit facilities for enough small business and independent firms to keep big business from becoming either stagnant or oppressive, restriction of mergers by purchase, and finally, revision of the patent laws. There is little in all this to question seriously, especially if one belongs to the school of sentiment which feels that small businessmen are *ipso facto* better citizens than captains of industry. Apparently, Wright is not impressed by the possible hazard to democracy from the pressure-group methods of these same little men organized.

The gist of his discussion of business cycles is that a planned economy could not remove industrial fluctuations unless it were willing to hold back new inventions and refuse to satisfy consumer wants promptly. In any economy in which growth and change are not checkmated, he holds, a certain amount of instability is inevitable. "An industrial society without a stabilization problem is likely to be an industrial society without economic freedom." So long as there are new inventions, new commodities, and resultant changes in consumer demand, the forecasting essential to a planned economy would

meet with insuperable difficulties. Stabilization would be bought at too high a price if it required us to curb our desire for the new look and the latest gadgets as soon as they appear on the advertising pages.² In a word, comprehensive planning would either have to restrain runaway demand, inferably by rationing and priorities—which most people do not like and which Wright therefore rejects—or it would have to retain many of the wastes and stabilize only by techniques already available.

He holds, however, that if we want a tolerable level of security, we cannot let inflation and deflation go their devastating way. His pragmatic solution is a "filling in" policy, a combination of timely pump-priming and continuous government expenditure for certain needed social services. If this sounds like an extract from the New Deal, no matter. It is practical Keynesianism, for the multiplier is just below the surface. "Suppose we undertook to rebuild the slums of every city. Would that not make a tremendous demand for durables and inject large amounts of purchasing power?" If this increased the government debt, so what! The significance of the debt is not its absolute size but its size relative to the national income. This may sound naïve, but we are spared the cliché that the debt is not really a debt, since we owe it to ourselves.

He has no use for egalitarian philosophy, and no fear of great fortunes, because it is "only three generations from shirtsleeves to shirtsleeves." Considering the dominance of the corporate form of business organization and the prevalence of family trusts, reiteration of this shopworn myth must be attributed to wishful thinking. Rather than try to increase consumer demand by redistributing income, he holds, we should encourage saving, investment, and production; but in Chapter 10 his brilliant argument for free international trade is based on the expectation of surplus savings in this country. As an outlet for them we shall have to have investment abroad. Does, then, capitalism require some kind of economic imperialism? Whatever the answer to that question, Wright does not look far enough ahead to consider what outlet for redundant savings we shall have when the backward countries are industrialized.

It would be difficult to arrange Wright's specific recommendations into a neat pattern. The book surveys too much territory, comes too hot off the bat, and is far too short to deal adequately with the implementation of his reforms or to integrate them into a consistent and logical whole. It has both the merit and defects of pragmatism in general. Dealing in compromises between values which if taken as absolutes may be incompatible, and concerned with differences of degree more than those of kind, his views seem at times disconcertingly ambivalent. This puts the critical reader on the spot, since he cannot be sure that he is interpreting the author fairly and accurately. Indeed, accuracy is an anomalous concept in connection with pragmatic compromise.

Wright holds, for example, that literal equality (which, so far as we know,

² But see his incidental reference to "false obsolescence," produced by excessive advertising, p. 122.

outside of Russia, nobody since Babeuf has advocated) would be impossible without abolition of the family. Hence, all we can do is to provide a "fair" rather than an equal start in the competitive struggle which is life. But can anyone define a "fair start" any better than a "fair wage"? Wright touches on race, but not sex, discrimination. He does not consider regional differences in resources, or the historical process which have made some cultures rich, others poor, in opportunities. What would he do with our own poor South, unable to finance a fair start for all its too numerous children? Federal aid for their education must be paid for by the productive workers of more prosperous regions. He would doubtless vote for this, since he says that "an adequate approach to equality [equity?] of opportunity undoubtedly requires great government outlay" for health, housing, and education; but to do so he would have to forget, *ad hoc*, his aversion to use of the tax power to lessen extremes between incomes. There is some point in his argument that progressive taxes, unless small new firms are granted sizeable exemptions, hamper the rise of the new man and the new enterprise; but what is the difference between taxing individuals according to their ability to pay, and taxing well-to-do parts of the country, like New York and Virginia, to provide better health and education in the Deep South?

Logical difficulties of this kind, giving rise to inevitable ambivalences, are characteristic of any pragmatism. The pragmatic approach, indigenous in Anglo-American gradualism, is the only method of progress we dare trust. A pragmatic culture has the faculty of gradually correcting inconsistencies, not merely through "drift" but through conscious modifications in the adjustments between its fundamental valuations.

Various contexts indicate that by "comprehensive planning" Wright means some form of collectivism.⁸ He takes insufficient care, however, to distinguish between comprehensive planning and the piecemeal planning necessary for the implementation of reform measures. If his thought appears on occasion a bit vacillating, it therein exhibits a characteristic of all instrumental pragmatism attempting to deal with an extremely complex situation. In steering between Scylla and Charybdis, it at times has to cut pretty thin. Wright himself notes that "the line between stabilizing the economy and setting up an over-all direction of it is extremely tenuous" and that "the two policies are easy to confuse." He might well have added that our ultraconservatives do their best to produce this confusion by branding every proposal for government aid or regulation a step toward the police state.

Specific recommendations for piecemeal reform are often less significant than the social philosophy—the system of value-sentiments—which lies back of them. Almost any liberal economist could draw up a list of remedial measures, which would differ from Wright's mainly in emphasis and detail. Likewise, almost any critic could find numerous points at which to disagree, both as to specific ends in view and as to the practicability of their imple-

⁸ "We will call comprehensive planning . . . the type of system . . . in which the general over-all pattern of development is planned and licensed in advance by a unified group of 'experts'—whether businessmen, bureau chiefs, or commissars" (pp. 3, 4).

mentation. Such criticism would be of secondary import. The main significance of the book lies elsewhere—in the first five chapters, in which the author posits the fundamental values he thinks an economic system should serve, and which, he believes, can be effectively served only by the profit system.

The economist who gets off the range of mechanical price analysis must realize that he is entering the still inadequately explored field of the psychology of motivation (needs, wants) and values,⁴ with which exchange and exchange value have only indirect connection and sometimes none at all. Attempts to fuse economics and ethics,⁵ to be even measurably successful, must be based on a general theory of human needs and their corresponding values. Judgment as to the effectiveness of a social system is essentially job analysis, in which the first and absolutely essential step is to identify, or to posit, the end or ends to be served by the system. Both economics and ethics in the last analysis are concerned with ends and means, with human beings and their resources. The resources are instrumental values. By themselves they have no significance or importance. The ends are intrinsic values, internal to the individual human being as states of feeling—at the level of consciousness, pleasurable experiences (satisfaction), or in a given situation the least unpleasant experience available. Instrumental values may stand in unmediated relation to intrinsic values—for example, the objective *condition* of freedom in relation to the subjective *sense* of freedom—or they may be far removed as stepping-stones, way-stations (John Dewey's "ends-in-being") in a long, complex chain of instrumental processes.⁶

Intrinsic values result from, or rather are, the satisfaction of needs, or wants, which constitute the "drives" to human behavior. No organism is ever more than momentarily in equilibrium, since it is subject to continually recurring needs or lacks. Its behavior is a constant attempt to maintain or restore equilibrium—organic balance on the physiological level, peace of mind on the psychological plane.⁷

⁴ It may be asked why "utility" would not be a more appropriate term. The answer is that utility, as thought of in economics (if the term is used at all), is always something external to the individual, as instrument to his "satisfaction." The satisfaction has importance or "value" in itself, without other *raison d'être*. Not so the instrument. In any case, the extensive philosophical literature on "general value" has avoided the term utility, and popular usage of late has followed suit.

⁵ By way either of an economic interpretation of ethics or an ethical (welfare) criterion of economy.

⁶ The best analysis of the nature of intrinsic and instrumental values with which the present writer is acquainted is given in the closing chapters of C. I. Lewis's *Analysis of Knowledge and Valuation* (La Salle, Ill., 1946).

⁷ A "want" or a need in this connection is a state of organic or psychic disequilibrium or restlessness. It does not necessarily produce a desire. In the terminology of present-day psychology, want and need are synonymous, and the psychologist avoids the economist's indeterminate distinction between needs, comforts, and luxuries. Organic or psychic equilibrium is the key postulate of C. Reinold Noyes' recently published painstaking and laborious analysis of the mechanism of human behavior. (See his discussion of "homeostasis"—his term for equilibrium—in his *Economic Man in Relation to His Natural Environment* [New York, Columbia University Press, 1948], Vol. I, pp. 29 ff.). A similar approach is followed by H. A. Murray, *Explorations in Personality* (Harvard

Scratch a "scientific" economist, and under the epidermis of his objectivity and rigid logic you will find a layer of welfare sentiment; that is, you will find a *man*, however loath *qua* scientist he may be to admit it. Every man is a welfare economist in a broad sense, though the welfare which concerns him may be only his own or that of the people with whom he prefers to associate because they "feel" (have the same sentiments) as he does. Wright, of course, is a welfare economist, in the more usual and reputable sense.

Welfare, however, is a slippery concept, and may be a weasel word. To mean anything as the aim of social policy, it must be given content, which in the final analysis must be the intrinsic values, the satisfaction of needs, the sense of well-being which comes with the recurrent restoration of organic or psychic equilibrium. The sixty-four dollar question is to what extent, if any, the basic needs can be identified by scientific research and empirical knowledge, or, on the other hand, how far needs—especially the "higher" moral, cultural, and esthetic needs which social policy should serve—can be posited only on grounds of sentiment and taste. The significance of this question is obvious: to the extent that needs can be empirically verified, something like a science of welfare is possible, but to the extent that they are posited by sentiment, welfare is a matter of subjective social philosophy. In the latter case there will be as many (frequently conflicting) "welfares" as there are cultures, for a social philosophy is an ideology, or system of valuations, and the relation between culture and ideology is a reversible reaction—a mutual cause-and-effect relation.

Inability to identify needs by any criterion other than subjective sentiments has been the rock on which welfare economics has repeatedly come near foundering. How can there be universal agreement on the content of welfare, in view of individual differences and conflicting cultures? It is a temptation to conclude that evaluation of the various intrinsic needs and values must necessarily be made by feeling or sentiment.⁸

Wright apparently shares this view, in his evaluation of science and the scientific method. In an early chapter he puts science on a pedestal because discovery and invention are the bases of the higher material plane of living which is "the one goal common to all factions in America today," but he later knocks science off the pedestal, because "scientific method, from its very nature, has almost nothing to say on the really important problems of life." This idea, common enough, that science can have nothing to say about end-values is reflected in the current best-seller anti-intellectualism which finds religion the only way out of the mess we are in; but it is untenable, at least so far as the basic survival and health (physical and mental) needs are concerned, as Wesley Mitchell pointed out twenty-five years ago.⁹

Psychological Clinic, 1938, reissued 1947). Murray subsumes the process of needs-satisfaction under the Second Law of Thermodynamics.

⁸ The present writer was inclined to this view some years ago in an article reviewing J. A. Hobson's *Economics and Ethics*. See "On the Content of Welfare," *American Economic Review*, June, 1931.

⁹ "The Prospects of Economics," in *The Trend of Economics* (1924).

Survival and health are prerequisite to the higher values—though Max Handman once remarked to the writer that there would be no lyric poetry if there were no neurotics!

Be this as it may, physiology, neurology, and the other organic sciences are supplying us with growing and increasingly accurate knowledge of the physical needs and biological drives; and psychology and psychiatry, while young sciences, give us even now sufficient empirical understanding of motives and attitudes to distinguish between those compatible with normal personality and social peace and those that are not. On the other hand, while science may reveal to us the influence of these primary drives on our simpler value sentiments, it is difficult to see how it can be a capable and accepted guide to the higher complex cultural values. Given time, perhaps it can; but just now, time is of the essence. Under threat of nuclear fission to survival itself and to the values which give survival meaning, not only an unusually large percentage of the public but some of the scientists themselves (though apparently not the psychologists) are turning to religion. Such escape is always sought in periods of *Sturm und Drang*. Possibly some hope for positive construction lies in this direction, but we could have more faith in it as a world unifier of sentiment if someone would show us how it is any easier to get a community of sentiment between the religion (or the ethics) of Marx and that of Christ or Mohammed than to reach a common standard of human welfare through science. Despite the present impasse,¹⁰ we are perhaps in the long run more likely to make progress toward a firmly grounded human welfare if we see, with Anthony Power, that "the greater the knowledge of science [given freedom of research], the greater the chance of scientific thought presenting an irrefutable and universal logic governing every field of activity and leading to the establishment of a sane world order,"¹¹ than we are if we rely too confidently either on supernatural guidance or on the intuitional insight of *Geisteswissenschaft*. At least, Wright might consider revising his idea that science can have nothing to say about the values constituent of human welfare. If economists in general would permit themselves more access to the empirical knowledge available on the psychology of motivation, they might be less confused and less dogmatic about the alleged absence of any relation between economics and ethics; but that would require them to tear down at least one watertight bulkhead in their mental hold.

It is not Wright's purpose in this book, however, to speculate on the possibility of a universal ethics or on science *versus* sentiment as basis for definition of welfare. Only incidentally does he touch on the problem of international peace, although peace, as essential to durable security, is certainly a fundamental value. He is concerned, rather, in analyzing the internal dangers which he believes threaten the cherished values of the American way of life—liberty, democracy, and (with far less emphasis) security. Scientific psychology undoubtedly regards some measure of freedom and security as universal human need; democracy is a complex of values, some intrinsic, some

¹⁰ Scientific agreement is, of course, impossible so long as Russian biologists and psychologists must conform religiously to the Marxian dialectic.

¹¹ Review of Aldous Huxley's *Ape and Essence* in *The Nation*, August 21, 1948.

instrumental, less amenable to scientific evaluation. But we do not go to psychology to support these values; whatever their organic roots, they are feelings or sentiments deeply ingrained in us by history and culture—so deeply that we mean to defend them, come hell or high water. Wright would probably say that we should do everything in our power to secure peace, but that in loyalty to our own basic values we should hew to the line and let the international chips fall where they may. It would be difficult to disagree with such a view, though we may not agree with him as to the values ancillary to liberty and democracy or as to the specific policies he recommends.

Even within our own American culture, however, Wright is on the horns of a dilemma—our value conflicts. To mitigate these conflicts and set us more firmly on the road of qualitative democratic progress, like everyone else he appeals to leadership and education to discover values and disseminate awareness of them. There is, of course, nothing else to appeal to, consistently with a democratic ethic. The present writer, at least, has no quarrel with Wright's strictures on the over-specialization and over-intellectualism of our present higher education; nor can anyone question that there must be leadership in the formation and perpetuation of moral (= welfare) sentiment, or that such leadership must come from an elite of some sort.

His treatment of leadership is necessarily somewhat sketchy, but has the merit—lacking in some students of the subject—of emphasizing the fact that leadership functions through persuasion and is, therefore, not to be confused with the power of office. But leadership is unequal to the task he demands of it, the development of "better qualitative standards of democracy." He relies for such leadership on an intelligentsia composed broadly of the "religious, professional, and intellectual groups." It is a bit difficult to imagine how we can expect from groups so heterogeneous in interest and social (not to mention economic) philosophy homogeneity of value-sentiment or agreement on social policy, though the threat of the atomic bomb may prove a powerful influence in diminishing the amount of energy which leaders, moral and political, habitually spend in combating one another. We shall do well, perhaps, not to expect too much too soon from either education or leadership, so far as agreement on the content of welfare (especially *whose* welfare) is concerned. Fortunately, the house of life is not built on a one-story plan. It is a far cry from the primary drives to the complex interests of the civilized man. Within a democratic and liberal culture, it is not only permissible and desirable, but inevitable, that the "higher" hedonic needs and interests should vary from person to person, group to group, and region to region. Without such variation, democratic culture might degenerate into the stale, dead-level of mediocrity, to the suppression of certain well-recognized personality needs, for example the need for status, recognition, distinction; and for variety of new experience.¹² Herein lies a deep significance of personal liberty—involving the right to be different as well as the right to "belong." Herein,

¹² Bearing on this line of thought is Wright's defense of rivalry and the competitive selection of ability. One may harbor some doubt, however, about go-getter ambition as a builder of "democratic character."

too, we may find the value of tolerance and forbearance, a certain pragmatism in moral sentiment and instrumental judgment, even as to the amount of economic planning compatible with democracy and liberty.

Some comment should be made on Wright's conception of progress. While capitalism, through the freedom it accords to science and invention, is the system most favorable to material progress, progress as "social betterment" involves moral and esthetic values. The aim of progress in general is not a fixed static ideal; it is "continual development" or "an ideal process of variation." The implication is that it is development towards "personal freedom and democracy of aspiration." Aspiration for what? Early in the book, it appears that most people are interested primarily in the material standard of living, and in the discussion of economic instability the profit system is praised because it gives the consumer what he wants when he wants it; but in Chapter 3, "The Meaning and the Method of Democratic Progress," in a passage remindful of Carver's "workbench" philosophy, we are asked to limit our wants. Our goal should not be the ending of competitive acquisition, but "the competitive acquisition of nobler things in a nobler way." "Not satisfactions but better wants" is the aim of social progress. Paramount among these better wants or drives is the "inventive-creative" urge. "The aim of creation is the creation of a creative world." This is sheer nonsense—or would be, did not Wright define a creative world as one "in which the loftiest and most satisfying¹³ creative impulses of the human being can be expressed." Here we escape hypostatization of a process into an end only by plunging into unadulterated subjective relativism. For who is to say what the "loftiest" or "noblest" desires are? Apparently Wright, the artist, for one, since on page 197 we are told that "the philosophy of life which the writer believes to be most fundamentally democratic, and the one hitherto most congenial to the modern man, is the philosophy of the artist—the searcher."

On what empirical evidence he assumes (p. 24) that "the inventive-creative urge and the ideal of continued development are more likely to appeal to the democratic mind" is not stated. Our impression is that most people are far less interested in "creation" as a process than in its results. Even among the elite, the scientist hastens to nail down the credit for a discovery he has made, the inventor loses no time in getting a patent, and the artist—however much he declaims on "self-expression"—sooner or later holds an exhibition.

Wright knows that "schools" of art and "academies" of intellectuals tend to discourage originality, and he is convinced that planning boards would similarly obstruct technological innovation. It does not follow, however, that all innovation, either technological or esthetic, is necessarily progress toward "better wants." It is not yet clear, for example, that television will prove either a moral or an esthetic advance—and there are some uncultivated dolts who prefer Rembrandt to Picasso. Wright's high valuation of technological progress is a reflection of the psychology of our current machine culture. One suspects that he has unconsciously erected his own personal artistic drive into a universal need, and therefore calls it democratic. One wishes that he

¹³ Although he has just said that satisfaction is not the goal of progress.

would offer some suggestion for enabling the millions of routine factory workers to satisfy this urge, if it is as essential to their welfare as he apparently thinks.

There is no similarity between Wright and the ass between two haystacks who starved because he could not decide which one to eat from. Wright knows what he wants—freedom for the creative urge—and his hunger for that sends him at once to the capitalistic stack, though he knows that there are nettles in its hay. The creative urge is, in fact, the pivot on which his whole defense of private enterprise turns. His argument that comprehensive planning would stymie that urge is arresting, but it is inconclusive. There is insufficient evidence; the case is not proved. Yet there is logic enough in his fears to make us cautious (to say the least) of the innovation of a planned economy, even though we may theorize that when we become civilized enough and are more equal to the exceedingly complex job of managing our own public welfare, the present system of delegating that management on a commission (profit) basis, like the old tax-farming system, may be superseded without loss of any eternal values.

A. B. WOLFE

Ohio State University

Dynamique Économique. By RAYMOND FLORIN. (Soissons: Imprimerie Saint-Antoine. 1948. Pp. vi, 115. 500 fr.)

M. Florin's essay in economic theory deals with the response of entrepreneurs to changing conditions and the effects of these responses on the equilibrium level and on the occurrence of disequilibria. The methods are those of marginal analysis, and mathematical notation is used fairly freely. Not only the differential calculus usually associated with marginalism but also and especially, the integral calculus is employed, the latter arising out of the evaluation of assets by discounting future returns.

The reviewer owns to some difficulty in fairly evaluating M. Florin's contribution for two reasons. In the first place, the bulk of the results are very familiar to the English-reading public through the work of Fisher and Keynes, but the author claims independence of all economists since Böhm-Bawerk (though there is a brief slighting reference to the two first-mentioned authors on page 25). In the second place, the author has adopted the somewhat unusual procedure of publishing a first edition which is not complete; the table of contents lists four chapters which do not appear in the text but which are promised for a later edition. Among other topics to be dealt with in these chapters are all issues of policy, the theory of international exchanges (including a tantalizing heading, "nécessité d'une balance commerciale déséquilibrée"), and the role of wage rigidity in crises.

The first part of the book is devoted primarily to definitions. Of chief interest is the remarkable attempt to avoid the problems arising from the existence of many commodities by means of Divisia indices of price and quantity. The interpretation of subsequent formal developments depends very heavily on the assumption that a Divisia index of output is truly a

measure of variation in physical magnitudes alone, independent of price variations. That this assumption is too facile is evident from the recent papers of Klein, May and Nataf in *Econometrica*. Another case where the author realizes difficulties but resolves them inadequately is the brief discussion of the measurability of utility on page 7. We need only demand, says the author, that utilities be comparable in the sense of more or less; but on pages 76-77, he speaks unhesitatingly of the diminishing marginal utility of stocks of money.

The second part deals with a capitalist non-monetary economy. For such an economy, he finds that, in equilibrium and at the margin, the rate of interest is equal to the sum of the following three magnitudes: the profitability in current prices of the best unit investment measured in current prices; the relative rate of change over time of the price of the best capital good as compared with the price of all capital goods; and the relative rate of change of the price of all capital goods in the current standard of value. The last term is nothing but Fisher's "appreciation," and the whole proposition seems to be a restatement of Fisher's that in equilibrium the rate of return over cost at the margin equals the real rate of interest. There is one important qualification, however. For Fisher and Keynes, the rate of return over cost (marginal efficiency of capital) is defined as that rate of discount which, applied to all future returns from the asset, will equate them to the current price of the good, while M. Florin considers only the current return from the use of the asset and the speculative gain in the immediate future. Under the assumptions of perfect competition and subjective certainty in expectations, M. Florin is unquestionably correct. But what Fisher and Keynes may have lacked in logic was probably more than compensated for in realistic observation. It appears to be true that entrepreneurs take into account the productivity of capital goods in the future before purchasing them. In the marginal logic, this can only be explained by assuming imperfect conditions in the market for used assets or uncertainty as to prices in the near future.

It is to be noted that the profitability in current prices of a unit investment measured in current prices is a quantity the value of which is independent of the standard of value; the same is true of the relative rate of change over time of prices of new capital goods with respect to prices of all capital goods. The sum of these two quantities is taken by M. Florin to be essentially a technological fact, though this interpretation is certainly open to serious doubt.

With the aid of the above-mentioned relation between the rate of interest and the marginal productivity of capital, the author derives a formula for the value of a capital good by discounting its future returns. On these bases, he argues from an assumption of diminishing marginal productivity of capital goods to a historical law of falling profits in periods of unchanged techniques. Much as Ricardo and Mill, the author foresees a period when investment ceases and the interest rate drops to zero. Unlike these classical authors, however, M. Florin regards this period as a very desirable goal, for output will be at

its maximum while the vanishing of the interest rate means that labor will receive the entire net output, thus solving all social questions. "Le problème économique que notre siècle a à résoudre est de franchir cette marche au seuil de l'âge d'or" (p. 68). It is overlooked that the vanishing of the interest rate means that the value of land, at least, will become infinite, so that the share of the capitalist will not vanish though it may take the exclusive form of rent.

In the third part the author considers a monetary economy. The most important consequence of the introduction of money is the Keynesian proposition that the rate of interest is determined as the marginal utility of holding the stock of money actually in existence. The utility of holding stocks of money arises (pp. 76-77) from imperfect foresight and the costs of obtaining credit or liquidating assets on short notice; this assumption is inconsistent with the subjective certainty and absence of transfer costs assumed elsewhere in the work, but the inconsistency is a common one (*cf.* the work of Professor Hicks or Dr. Lange). The rate of interest is taken to be proportional to the volume of output and to the price level and inversely proportional to the stock of money. This is a purely empirical assumption for which no evidence is offered. These results are combined with the formula for the value of an asset applied to money to express the price level of output in terms of the anticipations of total output, stock of money, and interest rate. The behavior of the price level over time is then studied under various assumptions as to expectations and realizations; the variety of results obtained suggests the need for a more general theory. The same analysis is also applied to find the effects of taxes on investment and on money. The latter, under the assumption of static expectations, will lead to an unchanged rate of interest but a rise in prices proportional to the ratio of the tax rate to the original rate of interest.

The author concludes with some remarks on the nature of economic disequilibria. In essence he suggests that they arise essentially from a discrepancy between the marginal productivity of capital and the real rate of interest. Although the discussion is not too explicit, the impression derived is that the author expects them to arise from unanticipated changes in productivity, very much along the lines of Schumpeter's theory (see p. 96), combined with the incorrect adaptation of wages (p. 110).

The reviewer noticed only two slips in mathematical reasoning: On page 22, it is asserted that a certain function possessed a derivative since it was continuous, which is not sufficient. On page 96, it is asserted in effect that a certain infinite integral converges because the integrand approaches zero as its argument approaches infinity; actually, the latter is neither a necessary nor a sufficient condition for convergence. Neither error had serious consequences for the main argument.

KENNETH J. ARROW

*Cowles Commission for Research in Economics,
University of Chicago*

Volkswirtschaftslehre—ein Abriss der wichtigsten Lehrmeinungen. By RICHARD KERSCHAGL. 3rd ed. (Vienna: Manzsché Verlagsbuchhandlung. 1946. Pp. xii, 208.)

This is one of the first books on economics to come out of postwar Austria. Though intended to "introduce the beginner to the main questions of theoretical economics," the little volume is much more than a textbook. Like most writers endeavoring to introduce economic theory, Professor Kerschagl is confronted with the vexing problem of whether to plunge the reader into a presentation and evaluation of prevailing economic analysis or to prepare the "beginner" by giving him a background in the evolution of economic ideas. The former alternative exposes the unsophisticated "beginner" to the pitfalls of negativism by filling him with controversial discussions, and may leave nothing but a vacuum. With the conviction that "that which is can only be understood by that which was," the author chooses the second road. "A History of Economic Doctrines" would therefore be an appropriate subtitle for this book.

Professor Kerschagl, who holds the chair of economic theory and finance at the Hochschule für Welthandel in Vienna and who is the author of a respectable series of books on economic methodology, monetary economics and banking, has, with admirable conciseness, summarized and interpreted the development of major economic thinking since the mercantile era. Professor Kerschagl's arguments and discussions are by no means elementary and leave a great deal of close reasoning to the reader. The book seems more appropriate for persons already somewhat acquainted with economics than for the untrained beginner.

The author's approach is that economic thought is conditioned by the economic environment and events of the time (in this respect, perhaps similar to Eric Roll's *History of Economic Thought*), yet he endeavors to separate those economic "laws" or "truths" whose validity endures from the economic views and doctrines which are solely determined by and apply to the economic circumstances in which they are written. Though striving for objectivity, the author's presentation in some places does not escape the flavor of his own rather vague idealism.

After only a few paragraphs on pre-mercantilist thought, the first part of the book deals with the mercantilists and the physiocrats in which the connections between the then prevailing politico-economic changes and the theoretical schools are neatly worked out. There is then one chapter each devoted to a description and explanation of the classical school, the German school, the socialist theories, and the Austrian school. In a somewhat unusual arrangement, the development of monetary theories and currency systems of the respective periods are brought together in an additional, separate chapter. The modern development of economic theory is covered in the next section, and the final chapter, in the form of an appendix, contains a discussion of Austria's contribution to the progress of modern economics. A rich and very helpful bibliography and index of names of authors concludes the book.

Throughout most of the book a subtle emphasis is placed upon two broad controversies accompanying the development of economic thinking since Ricardo; one, the dispute over inductive or deductive reasoning; the other, the time-honored dilemma of individualism *versus* universalism. At times these two controversies tended to run parallel, as in the feud between the German historical school and the Austrian marginalists. Although this controversy was mainly one on method, the historical school also attacked the classicists' mechanistic outlook and emphasized the organic concept of society. This, broadly speaking, corresponds to an attack on individualism in favor of universalism. (Much of this "attack" derives from a confusion of atomism with individualism.) To the Anglo-American reader, it would rightly seem that Professor Kerschagl has devoted too much space (relatively speaking, of course) to these opposing trends as well as to the whole German romantic thought. "Universalist" ideas were hardly of any importance in the English-speaking world and the vague, semi-mysticism of the romanticists is not taken too seriously by Anglo-American economists.

The conflict, however, between the deductive and inductive approach to economics has been a real one and is again conspicuous today (especially in the United States). The Austro-German "Methodenstreit" was resolved, after the "quarrelers" became aware of the fact that the two methods stand not in opposition to one another, but rather complement each other—a realization to which a few of our contemporary economists have, unfortunately, not yet come.

Although he strives to refrain from value judgments and subjective observations, the author is not always successful. For example, his personal lack of sympathy for current socialist thought and systems is unmistakably apparent in his chapter on socialism. He divides the development of socialism into three stages:—Utopianism, Marxism (scientific socialism), and finally socialism as an ethical postulate (or religion, in the broadest sense of the word). Socialist experiments, so we are told, may have succeeded in attaining equality of the masses, but they failed to produce economic betterment. Primarily because of this failure, modern socialism (the third stage) puts the goal of economic betterment into the background and considers its first task that of the salvation of the proletariat from the economic and moral yoke of capitalism. "Socialism becomes an ethical duty, a sort of religion . . ." which strives toward a new social order, not necessarily of economic progress, but in which all power is simply shifted to the working masses (p. 40). There seems to be little doubt that these remarks are intended to refer to present-day communism and Stalinism, but it is open to question whether the book, in its present framework, would not have benefited by an omission of such subjective observations.

The most serious shortcoming of the work under review is the almost complete absence of any treatment of recent developments in economic theory. There is, for instance, no mention of imperfect competition or monopolistic competition. Although Lord Keynes is treated in some detail, the discussion

does not proceed much beyond Keynes' *Monetary Reform* of 1923. The bibliography, likewise, though containing well over 700 titles, is sadly inadequate in references to recent economic works.

Although an index of authors is appended, a badly needed index of subject matter is lacking—this, despite the book's emphasis on ideas rather than individuals. (It is true that the table of contents is very detailed but that can hardly be substituted for a good index.) A few errors have slipped in. For instance, a total of about 24,000 banks is ascribed to the United States (p. 118), and in one place, Jevons is designated as an American (p. 165). These are not serious enough, however, to detract from the scholarship of the book under review.

There is no doubt in this reviewer's mind that, were the present volume more up to date, it would definitely warrant translation. The condensation of its material does not diminish the penetrating insight displayed in many parts. In addition, its particular approach and different emphasis would not only make interesting and informative reading for an English-speaking audience, but it would also provide a welcome stimulant to widen one's perspective.

JOSEPH GRUNWALD

Adelphi College

Readings in Economics: Principles and Problems. By WALTER ADAMS and LELAND E. TRAYWICK. (New York: Macmillan. 1948. Pp. xi, 520. \$3.00.)

This work is intended for the general introductory college course in economics. It can be used to supplement, but not to supplant, the traditional text or texts in economic principles and problems. Instead of an integrated exposition by a single author or several authors, the beginning student here meets many minds presenting various doctrines. The obvious advantage of this method is the ability to get firsthand the best of many statements of different points of view. The equally obvious and serious disadvantage is the unavoidable unevenness of treatment and the absence of syntheses, summaries and conclusions. To meet this deficiency, in part, the authors have supplied short continuities and introductions to their selections of readings.

Assuming the author's case for this type of introduction to economics, which of course is open to doubt and debate, the reviewer is greatly impressed by the skill with which this difficult task of selection and organization of material has been performed. The readings have been wisely and fairly selected; they give wide coverage and great variety; they stress essentials and keep within the horizon of the undergraduate. Although the book is well organized and follows the traditional pattern, it suffers from the almost complete absence of the vital body of economic theory, as developed systematically and didactically in most introductory courses. There is, however, one chart on price determination under monopoly conditions, and there are several articles on that and kindred topics.

Part One, "Principles," moves from an excellent introduction on the scope and method of economics, through production, stressing specialization, mechanization, and large-scale production, through markets, competitive

and noncompetitive, to the great issues of public control over monopoly, oversaving-underinvestment theory, and the full employment-mature economy controversy. Part Two, "Problems," features labor relations, credit and banking, business cycles, public finance and international trade. It is to be regretted that consumption is slighted. Value and distribution, the heart of economic theory, are ignored, or left to a companion text, or supplemental instruction. The reviewer feels that the material in Sections VIII and IX on credit and banking and on business cycles and price levels, respectively, should, from a pedagogical point of view, precede and not follow the earlier discussion in Part One on oversaving and underinvestment.

Sources include such famous writers and familiar quotations as those from Adam Smith on specialization, Böhm-Bawerk on roundabout production, Veblen on technology, Marx on communism, and J. S. Mill, List and Bastiat on protection and free trade. More modern writers include nearly all the great names of our own times, both in the United States and Great Britain. Alfred Marshall, alone, is conspicuous by his absence, which perhaps is another way of saying that the traditional emphasis on, or even inclusion of, value and distribution is missing. John M. Keynes, however, is represented by several excerpts from his more lucid writings, as is also John N. Keynes. For comedy relief and common sense, Mr. Dooley (Finley Peter Dunne) is revived to speak his mind on perennial economic issues. Finally, there are some useful selections from government reports, public laws (especially anti-trust and industrial relations legislation), and research studies, which give vitality and reality to the work.

Economic History; National Economies

Aspects of British Economic History, 1918-1925. By A. C. PIGOU. (London: Macmillan. 1947. Pp. viii, 251. \$3.50.)

In 1941-42 Professor Pigou, at official request, prepared this analysis of the British postwar transition from 1918 to 1925. It was designed as a set of memoranda for use in government departments concerned with problems likely to arise after the end of the more recent World War. The author had access to government files and to certain other data hitherto unpublished. He was assisted by a number of distinguished economists, including Mr. M. Dobb, Mr. D. Burn, and the late Mr. Erwin Rothbarth. The result is an unpretentious series of papers which, despite conscious gaps, presents a fresh and coherent account of the British economy in the six years after the Armistice.

Professor Pigou's essay into economic history is of interest in at least three different perspectives. First, it brings within the compass of unified analysis not only new data on the period, but also a number of specialist studies, which have appeared in other books and in the journals. Second, this volume is one of the few published efforts which attempt an inter-related account of a whole economy in movement over a short period of

time; and it is thus of distinct interest as an exercise in method. Finally, the book raises issues of comparison with present problems of British postwar adjustment and, as it was designed to do, helps to illuminate them, even by contrast.

Pigou first establishes cyclical turning points for the time period he is examining and designates them as follows: The Breathing Space, November 1918-April 1919; The Boom, May 1919-April 1920; The Slump, Summer 1920-Autumn 1922. The Doldrums, which follow, run from the beginning of 1923 to the crash of 1929, although Pigou's analysis ends with 1925. The rough and ready designation of these turning points will be the despair of analysts trained in the technique of the National Bureau of Economic Research; but they serve adequately the author's limited analytic purposes.

Within this general time framework the author examines: the course of employment; industrial production (with special reference to shipbuilding, housebuilding, and cotton exports); the breaking up of the government's wartime control system; the role of monetary factors; and finally, the course of real income and wages. In the analysis of the course of employment, the so-called Z.8 returns are valuable. These returns were based on questionnaires issued by the Ministry of Labour to employers, over the period from the beginning of the war to November, 1920. In some cases, the area covered was exhaustive, and in others the Z.8 figures represent an uncertain sample. Nevertheless, they permit a more sensitive account of the changing constitution of the working force in the immediate postwar period than has hitherto been available.

The theoretical framework which informs the analysis is that which the author developed in his more abstract writing on industrial fluctuations. The boom of 1919-20 is presented as a case in the unfulfilled expectations of over-optimism. The basis for the upswing is established in a backlog of capital investment which followed the war, much of which was once-for-all in character, notably shipbuilding and the replenishing of stocks. In explaining the downturn and slump of 1920-22, Pigou rejects a primary role for the monetary factor, which in his view responded to and then accentuated the depression. In his discussion of monetary factors, Pigou employs flexibly the vocabulary of the Cambridge cash-balances approach. His argument has evoked a nostalgic reply from R. G. Hawtrey (*The Economic Journal*, June, 1948) who contends for a more central place in the downturn for a restrictive Bank rate policy. Although theorists more recently educated may look for an approach in terms of the national income and its changing components, Pigou makes clear in a painstaking analysis the limitations of such data for the relevant years.

The postwar boom and slump was, of its nature, so international a phenomenon, and in the case of Britain so linked with export markets on the industrial side and with the New York market on the monetary side, that it cannot be fully dealt with on a national basis. Nevertheless, Pigou's account, frankly limited in its intent, is satisfying history and analysis.

In publishing this book the author was acutely aware of the limited analogy of his period with the likely sequence after the second World War.

In its final pages he draws only the broadest of lessons. Two striking differences in Britain's problem after the first world war as compared with the present position are the ease with which the balance-of-payments problem was then solved and the prompt return to prewar (or higher) levels of real wages. Most of the factors accounting for the difference are now familiar and widely agreed. Pigou's concluding chapter "The Upshot for Real Income and Real Wages" emphasizes, however, the striking favorable shift in the terms of trade from 1913 to the postwar years which cushioned the whole transition and may later have helped to lull British domestic economic policy into the inaction which characterized its course down to 1931.

Between 1913 and 1924 the favorable shift in the terms of trade for Great Britain was about 20 per cent. Real wages were probably somewhat above the immediate prewar level for the period 1920-22; and only slightly below from 1923 to 1925. Britain garnered the benefits, in cheap foodstuff and raw material prices, not only of wartime expansion in the Western Hemisphere, but also, which is often forgotten, a decade's massive investment before the war in Canada, the Argentine, South Africa, and Australia.

The decade before 1939 saw no such period of development of new areas and resources; while the wartime expansion of production in the Western Hemisphere has failed to outweigh the deterioration in supplies from other sources. Population has continued to rise. There have been complications of land reform and newly assimilated standards of food consumption. As a result, the cities have suffered serious relative disadvantage, as have countries which are predominantly urban.

It is too early, perhaps, to weigh exactly the relative importance of this imbalance in world production and prices in the years since 1945, as opposed to other forces determining the character of the European and world reconstruction problem. The evidence is, however, that this element, and its remedy, have not yet been fully appreciated.

W. W. ROSTOW

Geneva, Switzerland

Regional Planning in India. By R. BALAKRISHNA. (Bangalore, India: Bangalore Printing and Publishing Co., Ltd. 1948. Pp. 424. Rs. 20.)

The author describes this book as an attempt to coordinate locational dynamics with economic planning in order to arrive at a suitable regional plan for the economic development of India. The book falls disappointingly short of this goal, however, for the reader who considers economic development to be a broader concept than the industrial development with which *Regional Planning in India* is primarily concerned. It is disappointing, too, in its failure to appraise realistically the difficulties in the way of India's economic development, the need and desirability of which are unquestioned.

In this book the author has presented, with occasional details, a general plan involving the "substantial modification of the capitalistic system" which he believes to be a prerequisite for any successful effort in the industrial development of India on a regional basis.

After an initial consideration of location theory, the growth of industry

in India since late in the nineteenth century is discussed with particular attention to eight major and a few minor industries and their relative concentration or scatter. This section, and the succeeding ones which are concerned with the distribution of resources throughout India and with the wartime expansion of industry, will probably be of some interest to those unfamiliar with India's industrial economy. However, the discussion of concentration or scatter is in terms of outdated statistics, those for 1937 being the most recent. It is also without reference to the fact that India's total industrial population is probably not in excess of 10 million, with large-scale factory employment less than half that amount and inadequate to the needs of the country's 300 million people. Some of the author's conclusions regarding distribution of industry are of questionable practical value in the light of the foregoing.

Likewise, the writer's consideration of the possibilities of establishing industries at various points in India because some of the physical factors required by those industries can be found in such localities, minimizes unduly the difficulties in the form of untrained labor, inadequate transport, limited markets, and other factors which, until the present at least, have hindered such development or directed it to locations economically more feasible.

The author has thereafter included a discussion of the essentials of planning in general terms and of various of the plans, Bombay and others, which were advanced prior to partition, concerning the economic development of India.

The remainder of the book is devoted to a consideration of the effects of transport rates on regional planning, the need for State control of a wide area of economic activity, and the type of structure necessary in the reconstructed, largely state-directed economy, for which the author's predilection is evident at several previous points. The book concludes with a chapter on the consequences of partition written after it went to press and which in the nature of things is understandably superficial.

In this last chapter, some attention is given, however, to the need for improvement in Indian agriculture. Failure to make the point earlier and with greater emphasis is a major defect in a book purporting to deal with economic development on a regional basis. However rapid is India's industrialization, India will be predominantly agricultural for some time to come. However necessary it is to industrialize and to do so rapidly, the need for improvement in Indian agriculture cannot be ignored or long delayed. In an area with nutritional standards so low, with agricultural productivity comparing unfavorably with many regions of the world, with substantial dependence on the imports of food and other agricultural products, a widespread improvement in Indian agriculture would provide significant assistance to India's industrial advance. It is, moreover, one of the main points at which governmental assistance is essential, for private enterprise in Indian agriculture cannot effect the wide-reaching changes necessary in this field. With such agricultural development would be required improvement in both rail and road transportation, another important field for governmental effort. The multiplying effects of major and successful undertakings in these two

fields in terms of complementary and secondary employment should be far-reaching and should include industrial development, as well as other benefits.

As a practical matter one may wonder at the apparent confidence of the author in the State's ability to direct and to control so much of the economic development of India. The job to be done in that country is colossal and the talent, while of high order, must be spread incredibly thin. Statistical and other data necessary for planning on the scale indicated are inadequate and outdated. The difficulties inherent in these factors are either ignored or dismissed with little discussion.

EDWIN G. MOLINE

Washington, D.C.

Economic Systems; Planning and Reform; Cooperation

Are These Hardships Necessary? By ROY HARROD. (London: Rupert Hart-Davis. 1947. Pp. 178. 5 s.)

Ordeal by Planning. By JOHN JEWKES. (London and New York: MacMillan. 1948. Pp. xi, 248. \$3.75)

Planning and the Price Mechanism—The Liberal-Socialist Solution. By JAMES EDWARD MEADE. (London: George Allen & Unwin Ltd. 1948. Pp. xi, 130.)

These three books are evidence that the spirit of independent criticism is still alive in England. It may even be said that they are a contribution to that reassertion of faith in economic verities of which there has been increasing evidence among British economists since their release from the cramping influences of government service. Some of the difficulties in reasserting their economic faith, however, cannot be attributed to back-slidings encouraged during the long wartime silence, but are due rather to the doctrinal excesses if not actual heresies of the prewar era. Popular ideas on the unimportance of the state of the budget, on latitude to invest capital gaily regardless of the volume of savings, and on the theory of foreign trade, of which Mr. Harrod complains, may be argued to be a case of the Keynesian economics reaping where it had sown. This argument is strengthened by the fact that, while Mr. Harrod preaches that "re-education in the understanding of the basic principles of money and pricing is now needed," he will not himself re-admit the rate of interest as one of the regulators in the price mechanism. Professor Meade, on the other hand, goes a long way in reinstating interest rates as a part of the pricing mechanism, despite the fact that opening up the possibility of gains to speculators (who occupy a prominent place in his lively imagination) is offensive to his moral sense.

The central thesis of Mr. Harrod's book is that the main cause of Britain's troubles in 1947, when ground won during 1946 in the battle of recovery was lost again, was over-investment. Blame for the excessive capital outlay is placed squarely on the government, which had sponsored too many programs for the reconstruction and development of basic industries and too big a housing program, while at the same time failing to keep the capital schemes of private industry within the bounds imposed by the volume of national

savings. The consequence was "inflationary pressure," the term used by Mr. Harrod to describe an "excess of total demand over total supply at home." Employing the Keynesian analysis in terms of aggregates, he attributes this excess of demand to (or identifies it with) the excess of current domestic capital outlay over current domestic saving; and it is axiomatic that this in turn is identical with the adverse balance of current foreign payments.

The danger of over-simplification in this analysis is obvious, and it is in keeping with the Keynesian tradition. But simplicity was necessary to the fervour of the politico-economic tract that Mr. Harrod set out to write at white-heat. Although an English reviewer (Mr. F. W. Paish, *Economica*, February 1948) could claim that Mr. Harrod had seen his "major recommendations not only accepted but put into effect by the government, all within a period of four months," by the downward revision of its plans for capital creation, nevertheless the victory must appear dubious to Mr. Harrod. For his thesis was that, while another turn of the screw of austerity might be justified temporarily by the facts (if they were known), yet the adoption of a more sensible domestic policy that paid greater attention to the merits of free choice, combined with the right external policy, would hold out hope of improvement in the standard of life quicker than was possible under the policy of the labor government in its first two years. Policy has not changed and no significant relief from austerity is in prospect.

The necessity of Mr. Harrod's panegyric on the price mechanism even in a popular tract is indicative of his strong feeling on the contrast between the present system of controls and what he conceives to be Britain's real need. But it also shows to what a pass the neglect of the economic verities can bring us, when Mr. Harrod must solemnly acknowledge his indebtedness to another British economist for opening his eyes to the fact that rent restriction not only depresses the supply of unsubsidized new houses but encourages extravagance in the demand for housing accommodations!

Mr. Harrod is provocative in his examination of the international position. In the circumstances of European over-spending he asserts that the "allegation of a 'world dollar shortage' is surely one of the most brazen pieces of collective effrontery that has ever been uttered." He deals severely with the British policy that used up American dollars in releasing wartime-accumulated sterling balances and by failing to stop leakages of capital abroad. In fact he does not disguise his belief that it was dishonorable to use up the American loan by excessive capital creation at home and debt repayment abroad. Moreover, he argues ingeniously that the convertibility obligation of the Anglo-American Loan Agreement gave Britain a strong card in insisting on blocking sterling balances and that impending convertibility before July 15th "may well have saved the country hundreds of millions of pounds." But the most important point he makes on Britain's international position is the admission that in sponsoring the doctrine that each country must be free to adopt "expansionist domestic measures to maintain full employment at home" a nation may "carry out capital outlay programmes far in excess of the need to maintain full employment and of the savings of its own people." This is the first recognition by British economists, as far as I know, that the doctrine

of hands off domestic economic and social policy, which has been a British sheet-anchor in postwar international negotiations, may be inconsistent with the doctrine that good behaviour requires each country to have regard to the international repercussions of domestic policy.

His essay on "The Practical Consequences of Nationalising the Bank of England," reprinted as an appendix to Mr. Harrod's volume, may prove to be less ephemeral than the rest of the book. The anonymity that enshrouds British civil servants does not now hide the fact that Mr. Harrod was in a position in Whitehall during the war to appraise the influence of the Bank on economic policy. His judgment is that the Bank's "view may best be defined as the technician's view," and that "there may be wider objects of policy, the importance of which [the technician] is not well qualified to weigh." It would, for example, "be contrary to human nature to expect the Bank to be an enthusiastic advocate of the International Monetary Fund. It is bound to hark back to the world leadership and control which it exercised for so many decades before 1914." It is also unlikely to be a staunch advocate of a movement to free international trade but "to fall victim to the illusion that these fascinating war-time techniques [of economic warfare], handled with such art, can be applied in peace-time too." For these reasons Mr. Harrod believes that formal nationalization of the Bank was a mistake, because it "has gone far to resurrect the power of the Bank and puts it much nearer where it was before its practical dispossession in 1932."

Professor Jewkes' book is also a politico-economic tract, effective in its purpose of revealing the seamier side of planning from the British record, and kept on a high level of polemical morality. He is another wartime civil servant who, having shed his anonymity, is trying to interpret British central planning in the light of his wartime experience. His examination eschews the more technical economic analysis, and indeed this is neither necessary nor desirable for his purpose, which is to meet the advocates of planning on their own ground. Their arguments, while starting in and even maintaining a façade of economics, extend to politics and morals, and Professor Jewkes rightly believes that the "stakes are moral and spiritual." In this respect he is generous in admitting his indebtedness to Professor Hayek's *Road to Serfdom*.

There is nothing of the reactionary in Professor Jewkes' book. He accepts with approval the fact that the Keynesian economic doctrines offer "us a route towards the maintenance of full employment within a free society." He recognizes that "every sensible economy is a 'mixed' system" in which government has a part to play. But he reminds us that despite the wide acceptance of the new-fangled ideas on central planning they are of recent origin, and like most popular economic ideas they are not necessarily well-founded. He attributes the rapid spread in this case to (1) the desire to avoid mass unemployment; (2) "the growing feeling that men must be masters of their economic destiny"; (3) the belief that planning is "scientific"; (4) the assumption that State intervention can greatly increase wealth; (5) the craving for economic security; and (6) dissatisfaction with inequalities in the distribution of wealth.

The foundations of these beliefs are examined in chapters on the economic

arguments, on the characteristics of planners and planning (in which the oracular pronouncements of British statesmen are subjected to cold scrutiny), and on the moral and political features of planning. He sets up no straw men to knock down but examines the best arguments for central planning as such that he can find. His analysis shows that ignorance of the existing economic system of private enterprise, the refusal to compare its defects with the known defects in competing existing systems, and failure to look below the surface of blue-prints, all play their part in explaining the widespread appeal of central planning. Professor Jewkes destroys many economic and other illusions that contributed to the contagion of planning and he reveals central planning as a system that "ultimately turns every individual into a cipher and every economic decision into blind fumbling, destroys the incentive through which economic progress arises, renders the economic system as unstable as the whims of the few who ultimately control it and creates a system of wire-pulling and privileges in which economic justice ceases to have any meaning."

This may seem to many too strong an indictment, and it would be if it were applied immediately to Britain. But Professor Jewkes' observations confirm that the tendencies are at work. He shows that, despite the brave words of responsible statesmen about the maintenance of freedom in British socialism, the government has been pushed relentlessly to direct labor and to destroy enterprise and independent thought and criticism. The loss of liberties is exhibited by a list of petty and foolish restrictions, culled from "a casual reading of newspapers," which reflects both the rank inefficiency of bureaucracy and the "moral sickness of a planned society." It is exhibited even more strikingly by the revelation that 10,916 government officials in seventeen Ministries are "authorized to enter private houses and premises" to carry out inspections and investigations without a search warrant. It is charged that "snooping" requires a body of plain-clothed police hardly distinguishable from *agents provocateurs* and at best creates a "sordid atmosphere which . . . everywhere sets one man against another."

The moral weakness of the planned society is finally depicted in its obsession with material ends. Professor Jewkes concludes that "in the last analysis the spiritual content of planning proves to be a sham." And he contrasts the planned economy with the market economy in which "no one need ever claim that economic activity is the highest form of activity" instead of simply the means of allowing us to "get on as uninterruptedly as possible with the development of the real art of living and the discovery of those forms of human relations which will bring us the ideal society."

Professor Meade's subtitle implies that he is the socialist among these three authors. Apart from the question, however, whether "liberal-socialist" involves a contradiction in terms, it is difficult to see in what respects if any he is a socialist. His book grew out of a—presumably critical—review of a pro-planning volume by Sir Oliver Franks. He confesses that he is no planner if the latter "necessarily believes in a quantitative programme of output, employment and sales for particular industries, occupations and markets and the

exercise of such direct controls by the State as are necessary to carry this out." Professor Jewkes argues convincingly that these earmark the beliefs of the planner and socialist. Professor Meade confesses further that he is only a planner if the "anti-planner necessarily denies that the State should so influence the working of the price mechanism that certain major objectives of full employment, stability, equity, freedom and the like are achieved." Professor Jewkes would say that these objectives, properly defined, earmark the liberal. And, in fact, Professor Meade's conception of his thesis, and the showing of his whole book, confirm that whatever he may once have been his economic doctrine, is now in the main liberal.

His thesis is that "a large measure of state foresight and intervention is required to guide the economy from war to peace, to prevent inflationary and deflationary pressures, to ensure a tolerably equitable distribution of income and property, and to prevent or to control the anti-social rigging of the market by private interests, but that these objectives can be achieved in an efficient and a free society only if an extensive use is made of the mechanisms of competition, free enterprise and the free market determination of prices and output."

Unfortunately no systematic attempt is made to subject the record of the Labour government to these tests, and therefore Professor Meade's liberalism and his socialism remain untested. What stands out in his book, however, is the ethical note in his thesis. He is for "the unthrottling of the incentives of private initiative" but he dislikes the idea of "scarcity windfall profits" that may be associated with the use of the price mechanism. No attempt is made to define his concept of equity in distribution or to solve the problem of generalizing his and all the innumerable other concepts of "a tolerably fair distribution of money income and property." Nor is there any attempt to assess the total probable effect on incentives of state intervention for the purpose of removing the element of chance in the economic universe. He has too little faith in the price system to assume that if speculators can make money easily, all will want to cash in and the "opportunity" will melt. And, finally, he does not produce any support, other than a wordy and almost meaningless quotation from Mr. Atlee, for the statement that the British system represents a middle way between the communism of the Soviet Union and the capitalism of the United States—a cliché that has now worn very thin.

These features give the book, despite much good economic analysis, an air of unreality. This is enhanced by a tendency to over-estimate the practicability of theoretically *recherché* devices, such as the auctioning of import licenses as a means of diminishing the discriminatory effects of import controls, or to over-elaborate his analysis. An example of the latter occurs in the discussion of foreign trade policy, which is the best part of the book. By his dictum that the adjustments from exchange depreciation by a group of deficit countries are likely to occur (on the implied assumption that the rest of the world is small) mainly in the imports of the group, whereas those from depreciation by a small single country are likely to occur mainly in that country's exports, he gives a false appearance of contrast. Depreciation by the group of coun-

tries represents appreciation by the rest of the world, and the smaller it is the more likely is appreciation to operate on its exports (which are the group's imports) to decrease them, just as depreciation would have increased them.

There are so many good things in his analysis of the international problem that it is a pity Professor Meade is not more explicit on his own views of British policy. He does not seem to me to come out as flat-footedly as he should against discriminatory import restrictions in view of his own shattering argument against them. He even gives the impression that if Britain could get away with discriminatory monopsony it would be all right with him—which for such a stern moralist on domestic monopoly issues is surprising. I sense that he suffers from a complaint that has afflicted British policy-making for a long time, the failure to make a clear distinction between the unescapable shorter-run problem of the transition from war to peace and the ultimate aims that give meaning to the transition. He wants teeth in the International Monetary Fund to insist on appreciation or depreciation in the interest of flexible exchange rates, but he does not ask whether international obligations extend to domestic behaviour that will prevent deficit countries from getting into or remaining in that position. Yet this question will remain pertinent long after the present difficulties of European countries, whether or not they are all the heritage of war, have been overcome.

In a more subtle way the same disease prevents Professor Meade from being explicit enough on the virtues of some countries simultaneously lending and borrowing, to do justice to the importance of restoring the network of international lending. Abstracting from political considerations, Britain should be glad to borrow on longer term from America and to lend for shorter periods to the whole world. British banking as well as technical know-how is still needed. New York has not yet duplicated all London's banking skill, and the release by appropriate British government action (even if it included more liberal travel abroad) of the entrepreneurial spirit in merchant banking would pay handsome dividends direct and indirect, to Britain and to the world. But the obsession with the short-term problems that make exchange-control inevitable inhibits all thinking on the long-run problem of encouraging capital export.

Each in its own fashion, these three books exhibit the vitality of economic thinking in England and show that freedom of expression is still open to those who make bold to be critical, despite Professor Jewkes' very proper fear for independence in the socialist state. It will be a sore blow to faith in democracy if writing of this kind fails to have any effect on policy.

REDVERS OPIE

The Brookings Institution

Economic Security and Individual Freedom: Can We Have Both? By ALBERT LAUTERBACH. (Ithaca: Cornell Univ. Press. 1948. Pp. iv, 178. \$2.50.)

It is doubtless all to the good that in times such as the present when so many fundamental social and economic issues are being subjected to critical examination everywhere the general reader should have a wide choice of

popular manuals to which he can turn as he seeks to understand the heated controversies of today. Many to whom these things have been a matter for concern for some time may perhaps feel that the general issues have already been adequately and often better covered by earlier writers, and that it is now high time to go beyond the vague generalizations to which popular manuals must always of necessity confine themselves, but the young voter of today would probably find that a book written a few years ago read somewhat strangely and might prefer something bearing the datemark 1948.

A reviewer is therefore not entitled to reproach Professor Lauterbach for having induced him to spend some time in working through an analysis of the interrelated problems of economic security and individual freedom without making any notable addition to the complex of ideas and feelings which had been left in his mind by earlier reading and reflection in this field. But at the end of the process the reviewer is in some embarrassment to decide what he can usefully say about Professor Lauterbach's book. It would profit little merely to list on one side the points on which he agrees with the author, and on the other those from which he dissents. But any other course is made difficult by the fact that there is not enough tough substance in the argument to make it easy to get a firm grip anywhere, unless one is prepared merely to rehash controversies, many of which have already been worn rather threadbare.

Professor Lauterbach has a commendable sense of the urgent necessity for mankind to learn its lessons quickly, but the precise content of the lessons to be learned remains obscure. He is firmly convinced that economic security and individual freedom are not inconsistent, and rightly insists upon the confusions of thought which the uncritical use without precise definition of words like socialism and freedom often encourages, but there is no penetrating analysis of the implications of the widespread and quite understandable claims for economic security, and little help is given to the unskilled reader who is anxious to avoid the confusions of thought against which he has been warned.

The concept of social planning may, or may not, be "a good thing," but an author who repeats with approval a quotation in which it is assumed that the fact that "The Ford Motor Company plans" is relevant to the discussion is not giving the young voter of 1948 any real assistance in learning the lessons which press so urgently upon him. It should not be thought enough in 1948 to affirm that "what really matters is an effective control of organized society over economic development." The discussion of methods for making control effective, important though it sometimes may be, is essentially merely a matter of machinery. What is really important is to know what the machinery will do, and how it will do it, and on these urgent, strictly elementary questions, Professor Lauterbach offers little guidance.

A general economic plan, he tells us, would start out from a comprehensive picture of the resources available for use, compare these resources with the patterns of national consumption, and with the purchasing power available to the various groups of consumers, and then would "finally attempt to ar-

range both the use of the resources available and the distribution of national income among the major social groups in such a way that it all 'comes out' on an adequate level of supply and consumption" (italics supplied by reviewer). Such vague, broad generalizations were perhaps pardonable when discussions such as this were necessarily directed mainly to the future, but in recent years sufficient experience has been accumulated in many countries to justify us in expecting that writers in the field will take some pains to make clear the difference between statistical analyses, however ingenious and penetrating, and effective economic policies.

The present reviewer finds no difficulty in examining on its merits specific proposals for state ownership of particular industries. Until he was over twenty-five he had never seen a railway train that was not owned by the state, so that the state control of railroads does not seem to him an exciting issue. He agrees that the violent economic fluctuations of the last twenty years were scandals which should not and need not be allowed to recur. But general arguments in favor of "social control of economic life," whether or not they are defective in detail, seem to him objectionable mainly because they usually fail to direct attention to the real economic problems which confront the world today. Professor Lauterbach is aware of the danger of continuing to fight the last depression, but though our current problems are highly relevant to the relationships between economic security and individual freedom, he has very little to say about them.

ALLAN G. B. FISHER

Washington, D.C.

Stalin and German Communism—A Study in the Origins of the State Party.

By RUTH FISCHER. Preface by Sidney B. Fay. (Cambridge: Harvard Univ. Press. 1948. Pp. 687. \$8.00.)

The sequence of events which led to the russification of the Communist International and the abortive intervention in German communist affairs assume added significance in the light of Soviet Russia's aggressive expansion during the years 1945-1948. Accordingly, *Stalin and German Communism* is a valuable and timely contribution to current history of world affairs. Though this book deals with controversial issues and personalities, sinister motives and lofty ideals, which are not readily comprehensible to the American public, it is an interesting, readable history of the German and Russian communist parties from 1918 to 1929. The author is largely concerned with recording the subterranean methods used by Stalin in achieving control of the parties in these two countries and the gradual entrenchment of National Bolshevism in Soviet Russia.

During the first world war, as a young student at the University of Vienna, the author joined the Social Democratic Party of Austria and became an active leader of these "Left Radicals." The Bolshevik revolution in Russia stirred the idealism of these "Left Radicals." Shortly after the collapse of Austria-Hungary, a Bolshevik delegation from Moscow, disguised as a Red Cross mission, helped her to found the Communist Party in Austria, which

became affiliated with the Communist Third International—*Comintern*. Within a year, discouraged with the slow progress of the party in Vienna, she moved to Berlin, which she believed had become the real center of the revolutionary struggle in Europe. In November, 1921, Ruth Fischer was elected chairman of the Berlin Reichstag. From 1924 to 1926 she was a member of the Comintern Presidium, where she defended the views of the Left Opposition led by Leon Trotsky and Grégory Zinoviev. She incurred the wrath of Stalin because she revolted against the totalitarian methods to transform the Comintern into an agency of the Russian State Party. In 1926, she was expelled from the German Communist Party which had fallen into the hands of Stalinists. When Adolf Hitler seized power in 1933, she fled to Paris and in 1940 came to the United States.

World communism as currently directed by the Kremlin adds credence to the author's thesis that fascism is an aberration from communism and not its antithesis. First by imitation and later by absorption, the nazis took over the institutions, the slogans, the methods, the brutalities of the Stalinized German Communist Party. This documented study explains also that the present Socialist Unity Party in the Russian Zone of Germany is a combination of the most effective elements of its two parents: the nazis and the communists. Hence, the book is an authoritative record of some of the most significant events of our generation.

♦ Bolshevism, as envisaged and interpreted by Lenin, the intellectual godfather of communism, was fundamentally different from the National Bolshevism later expounded by Josef V. Stalin. Mrs. Fischer makes it abundantly clear also that this basic divergence was reflected in their diametrically opposed attitudes towards Germany. Lenin and his co-founder of the Soviet System, Leon Trotsky, had hoped that the real drama of the World Revolution would unfold in neighboring Germany, where the workers of the most industrialized nation in Europe would assume leadership of the new world struggle for socialism.

Lenin contended that socialism in Russia was possible only in alliance with one or more technologically advanced countries, in particular with Germany. Since Russia was a peasant country, this alliance meant specifically that the Russian peasant would be induced by the incentives that industry offered to change his centuries-old way of life, to become first a farmer and then a cooperative farmer. Moreover, in the Left Wing of the Social Democratic Party in 1914, Germany had one of the strongest and most conscious anti-war movements. But the German revolution of 1923 was abortive and Lenin died. In his place, Stalin stepped in as the apostle of a new Russian nationalism and of National Bolshevism and builder of the totalitarian Communist Party machine and of the Russian police state under the guise of proletarian dictatorship.

The history which Mrs. Fischer records, covering the period 1917-1929, is a notable addition to the contentious and multitudinous literature on the inner factional struggle for power of the Communist Parties in both Russia and Germany and for the early control of the Communist International. She

cites chapter and verse, both from memory and research, to show how Stalin transformed the Comintern and the German Communist Party into agencies of the Russian State Party and how foreign communists were transformed from revolutionists into tools of aggressive Russian nationalism and of its state policy. These events assume added significance in the light of Soviet Russia's current aggressive expansionism and of the "cold war" between East and West.

Under Stalin's direction, terrorism as an instrument of national policy to achieve and retain supreme power has become so institutionalized that it defies comparison. The coterie of men who direct the destinies of the State Party are dangerously fanatic idealists and their disciplined devotion, exemplary energy and loyalty to Russia and its infallible *vozhd* (leader) constitute the combined threat and challenge to free men everywhere. The methods employed recently to dominate Roumania, Poland, Hungary, and Czechoslovakia are parallel to those used by the Stalinist in dominating the German Communist Party. The pattern was set in Germany twenty years ago.

In presenting a systematic record of this sequence of events in its contemporary perspective, Mrs. Fischer offers valuable explanation that will help in understanding the dynamics of Soviet Russia's expansion. The preface by professor-emeritus Sidney B. Fay and the publication of this book by the Harvard University Press enhance the authenticity of Ruth Fischer's story.

Business Fluctuations

Trends in Output and Employment. By GEORGE J. STIGLER. (New York: Nat. Bur. of Econ. Research. 1947. Pp. 61. \$1.00.)

This volume is an interim review of the National Bureau of Economic Research studies of production, employment, and productivity from 1899 to 1939. These studies have now been carried on over ten years and twelve separate reports have been issued. The fields already covered are manufacturing, mining, agriculture, and gas and electric utilities. Further reports dealing with transportation and the service industries, and a comprehensive summary and interpretation will follow.

These reports include indexes of the physical volume of production, of employment, and of productivity for each of the major industry groups mentioned, and for many subgroupings, including about 150 individual manufacturing industries. While these are not the only such indexes available, they are the most comprehensive and precise.

Mr. Stigler has combined the separate indexes computed for each of the major industry groups into composite indexes and briefly analyzed their behavior. (He includes also unpublished indexes for steam railroads.) He is careful to point out many limitations of these statistics. It has been impossible to make adjustments for changes in the quality of commodities and of labor, for the shift of activities from the household to the factory, and for unem-

ployed workers "attached" to these industries. Despite these limitations, the indexes constitute the major contribution of these studies.

Of the substantive findings, the most significant is that while output in these industries tripled, man-hours of employment remained about the same. That is, with the same labor input, these industries produced three times as much in 1939 as in 1899. In view of the fact that they cover about forty per cent of total output in the United States, we have here an important and impressive measure of economic progress since the turn of the century.

The indexes show that the rise in production occurred during the first thirty years of the period covered. Output during the 1930's was relatively low; in fact, not until the last year of the decade was the 1929 level of production again reached. Productivity, on the other hand, rose most rapidly during the 'thirties. This intriguing relation is, regrettably, left for future exploration.

Two other findings may be mentioned. First, the relative importance of manufacturing among the six industries covered increased substantially over the forty-year period, mainly at the expense of agriculture. Manufacturing output advanced from about 50 to a little over 60 per cent of the total for these six industries, while agricultural output declined from over 30 to about 15 per cent. A corresponding shift took place in employment. And second, changes in productivity have been very uneven, over time and among industries. Thus, the average increase in output per worker per decade for these six industries was 14 per cent, compared to almost 50 per cent between 1919 and 1929. For individual manufacturing industries the percentage change in output per worker between census years varied from -18 to $+36$, while the standard deviation of these percentage changes fluctuated between 3.2 and 7.6 per cent.

Mr. Stigler stresses the importance of distinguishing between changes in output per worker and changes in efficiency. Changes in efficiency are defined as changes in output per unit of all the factors of production rather than the factor of labor alone. To illustrate the significance of this distinction, Mr. Stigler presents some exceedingly rough measures of changes in efficiency for broad groups of manufacturing industries. They show increases that are somewhat smaller than the increases in labor productivity. As might be expected, they indicate that changes in labor productivity are poor approximations of changes in efficiency in industries where labor costs are small relative to total costs.

This study is a welcome review of ten years of work on a major economic project. A definitive evaluation of this volume, and indeed the whole project must, however, await the publication of the remaining volumes, and particularly, the final summing up.

JULIUS SHISKIN

Washington, D. C.

Arbeidsduur en Welvaartspeil. (Hours of Labor and Level of Prosperity.)

By P. J. VERDOORN. (Leiden: H. E. Stenfert Kroese's Uitgevers-Mij. N. V. 1947. Pp. 275.)

In this new study Dr. Verdoorn, known by his *The Increasing Rigidity of*

the Cost of Production,¹ is attempting to systematize and analyze the so far rather heterogeneous elements concerning the demand for and supply of hours of work which are found in economic literature.

The author starts with an analysis of the "optimum" hours of work. For the employer, the optimum hours are those for which the weighted productivity of the marginal worker and of the marginal hour are equal. The demand for hours of work is affected by changes in (a) the relationship between the productivity of the marginal worker and that of the marginal hour, (b) marginal costs in their mutual relation, in particular marginal wages and (c) the volume of production.

Concerning the supply of hours by the workers, Verdoorn demonstrates how the curve extends from the lower right to the upper left, the horizontal axis representing hours per workday and the vertical axis the hourly wage rate. Dynamically, many factors such as the difficult-to-measure preference for leisure may give the curve a different shape.

After a historical summary on hours of labor in several countries (written by Mr. J. E. van Dierendonck), the author further analyzes the theoretical aspects. With Cassel he rejects the disutility theory because an increase of wages is usually accompanied by shorter and not longer hours. While Cassel bases this rejection also on the absence of influence of the individual on hours of labor in modern labor contracts, Verdoorn supports Frisch's point of view that in collective wage agreements an average opinion of the group of workers involved is visible.

Applying the theory of imperfect competition and using indifference curves, the author constructs more refined curves of demand and supply of hours of labor and demonstrates how different points of "equilibrium" are possible which form an "equilibrium zone."

The author, in chapters on the relations between hours of work and shortage and abundance of labor, respectively, examines the effects of changes in work hours on production, employment, income, wages and prices. Interesting statistical observations on the effect of shorter hours on labor productivity are quoted. Under conditions of high employment and shortage of labor, a choice can be made between longer hours and additional workers. In this connection the author points out the necessity for research work in individual industries. In times of acute commodity shortages, an advantage of longer hours over additional marginal workers is that in the latter case the increased wages, necessary to attract this marginal manpower, will spread to the other workers and thus enhance inflationary tendencies as opposed to the limited effect of overtime pay.

Verdoorn gives an astute analysis of the relation between labor abundance and hours of work. The effects of diffusion (spreading) of work are distinguished in primary and secondary reactions. Primary reactions concern the interrelation between hours and productivity, secondary reactions are, *inter alia*, those affecting demand for the product in question as a result of changed production costs. As an instrument of business cycle policy the

¹ Reviewed in this Journal, September, 1947, p. 675.

author would like to see a general diffusion of labor (if any, depending upon the circumstances) combined with a government subsidy to the workers. Such a subsidy should compensate the decrease in each worker's hours and weekly pay. The subsidy is preferable over fluctuating tax rates à la Hansen because the volume of purchasing power can be more accurately fixed, and a certain stability in tax rates, creating a favorable atmosphere for business, can be maintained. In many respects shorter hours are also better than public works, *inter alia*, because they can be initiated or terminated at any time, and since they can be applied where unemployment prevails and without transfers of workers to different work. Furthermore, a subsidy will have an immediate and favorable effect on consumption.

The treatment of the imperfections of the market for work hours and the "leisure preference" might—to this reviewer's mind—have been more extensive. Also, the book might have been somewhat more lucidly organized, for instance by putting the historical survey in an introductory chapter or in the appendix (which has an interesting mathematical analysis of the influence of hours of labor on productivity).

This is a stimulating book and the treatment of the subject is refreshing. It is regrettable that no English summary was provided.

JOHAN KAUFMANN

Washington, D.C.

A Creative Capitalism: Intended to Reveal Where Depressions Start, Where Lasting Cure Must Begin, and How Cure Can be Had Within the Capitalistic System of Private Enterprise. By JOSEPH E. GOODBAR and LORENZO U. BERGERON. (Boston: Boston Univ. Press. 1948. Pp. xii, 376. \$3.75.)

Three ideas in the study of economic change which have been given major attention in recent years are income flows, leakages, and secular stagnation. Starting with these ideas, differing conclusions will be reached depending on the type of simplification employed and the lines of causation accepted. These three ideas are the basic ones in Goodbar and Bergeron's book, although they never employ the words leakage and secular stagnation.

The amount of current selling price on current output is held to outrun the amounts of buying power in use by individuals. Under-disbursements by business and over-saving by individuals are said to develop in prosperity.

The authors propose incentive taxation and "safe-keeping deposits" to keep these discrepancies from occurring. Incentive taxes are to be prohibitive income taxes levied against businesses and individuals if cash outgo is less than cash intake. To permit the purchase of existing property and securities, it is proposed that the burden of expenditure pass on to the seller of such property. If no other good use can be found for funds, government safe-keeping deposit is to be available, making simple the avoidance of the penalty tax. The funds so obtained are apparently to be interest-free for two years and thereafter levied an annual charge of two per cent for safe keeping, and

are to be employed for reforestation, water control, soil conservation, and generally for resource conservation and development, but not to enter into competition with private industry.

The authors are impressed by the evidence given in the TNEC hearings that expenditures are likely to be in the magnitude of ten billion dollars short at full-employment levels. One would think, therefore, that a constant increase in the national debt should be expected, although possibly at zero interest. No mention is made of this prospect, but on the contrary, it is proposed that a five per cent tax be levied on value added to greatly reduce the war debt.

The reviewer must conclude that unlimited faith is placed in the effectiveness of incentive taxation. Difficulties not faced are the potential inflationary situation created if, as a minimum, "expenditures" must equal income, while in an expanding society, many units must at times spend much more than their intake; failure to provide any offset for the net expenditure decline which will occur with a decrease in the number of new businesses formed and an increase in the number failing. The safety valve of government expenditure on resource conservation and development, called into operation only by increase in safe-keeping deposits, could be implemented only slowly and once started not readily cut off. The reviewer was impressed along these lines when viewing Missouri Valley projects in August, 1948.

The authors have no faith in the use of advance forecasts to guide in timing public projects. It must be concluded that the probable outcome would be slowly developing public works to offset recession. Certainly if recession got under way, the incentive tax would merely drive excess funds into safe-keeping deposits.

The reviewer can but admire the authors for attempting to set up a type of control which would avoid dependence on the government and the enthusiasm with which the proposals are presented. No one can quarrel about the importance of some modicum of stability. It is indeed unfortunate, however, that the work of others was largely ignored. Particularly helpful would have been a study of Ruth Mack's savings tax, Arthur Dahlberg's deposits tax, and C. W. Hazelett's incentive tax. The failure to consult such studies possibly may be accounted for by disdain for the work of professional economists.

In spite of mistakes which economists have made, if the authors had known more about economic thought they might have saved themselves such difficulties as necessarily arise from assuming that prices are merely the result of adding up costs and a profit margin. The difficulty is particularly evident in analysis of the effect of depreciation. They say that accounting, greatly expanded by the income tax, has resulted in higher prices to allow for depreciation. This they believe is an important part of our present difficulty.

Money and Banking; Short-Term Credit; Consumer Finance

A History of Savings Banks. By H. OLIVER HORNE. (London: Oxford Univ. Press. 1947. Pp. xii, 407. \$5.00.)¹

The primary purpose of this volume is to present the history of the trustee savings banks of the British Isles. In developing this narrative the author sketches the history of other types of savings institutions and of the thrift movement. The origin and development of savings banks were contemporaneous with and influenced by the profound social changes which occurred in the late 18th and early 19th centuries. Savings banks were organized primarily to promote thrift among the poor and, prior to 1810, were usually started and supported by the charitable rich. In 1810 a savings bank incorporating mutual principles was established in Scotland. Within a few years numerous mutual savings banks were in operation in the British Isles and in other countries, including the United States.

In the British Isles, especially in England, there soon developed a demand to place these banks under state control. The first such law was passed in 1817. Subsequently, at least twelve comprehensive and several supplementary statutes were enacted. As a result of these laws the trustee savings banks (except for some in Scotland), although independent of the state, have become auxiliaries to it. The services rendered by these banks may be grouped in four categories, three of which are departmentalized.

The Ordinary Department was created by law in 1817 and is found in all trustee savings banks. In terms of balances due depositors, it has always been the most important and, in recent years, these balances have approximated 65 per cent of the total. The deposits are forwarded by the banks to the National Debt Commissioners, who are required to invest them in government securities. The banks are merely conduits! The government guarantees the return of the moneys transmitted to it together with interest at a fixed rate. Since 1888, the rate of interest paid the banks has been 2.75 per cent; to the depositors, 2.50 per cent. The difference is used by the banks to pay their expenses, which are carefully controlled by the Commissioners, and to build reserves.

Deficits and surpluses of this department are absorbed by the government. From 1817 to 1948 deficits were incurred in 85 years, all before 1909; surpluses, in 46 years. The deficits resulted primarily from the government policy, influenced by the savings banks, of paying higher rates of interest than investment returns justified in order to promote thrift. Over the entire period, however, the surplus has been many times greater than the deficit. The author questions the soundness of a policy which enables the government to profit on savings of the poor and presents arguments in favor of a higher fixed rate. No analysis, however, is made of interest computation on other bases; e.g., on basis of investment returns.

The Special Investment Department was created by law in 1828; was not used until 1847; and is currently limited, by a law passed in 1904 to the

¹ Published posthumously.

larger banks. In recent years the balances due depositors of this department have approximated 25 per cent of the total. The deposits are invested by the banks in tax supported securities of local governments; in direct and government guaranteed securities; and, since 1934, in certain corporate securities. There is no government guarantee to repay the deposits or the interest thereon. To the depositors, the advantages of this department are a higher rate of interest and the avoidance of the deposit limitation (£2,000) prescribed for the ordinary department. The activities of this department are subject to "almost unfettered" state control. Pursuant to law the National Debt Commissioners, for example, select the securities eligible for investment, give prior approval on all purchases and sales of securities, control expenses, and approve the interest rate.

The Stock Department was created by law in 1880. Through this department the banks perform the services of security brokerage firms; they, however, deal only in government securities. In recent years the balances due depositors of this department have approximated 10 per cent of the total. Through the Service Department persons may, for example, purchase government annuities and insurance, receive financial advice, and purchase railroad tickets.

Many American writers have stated that the trustee (mutual) savings bank system of the United States and the trustee savings bank system of the British Isles are similar. Except for management by trustees, the two systems have very little in common. In the United States the trustees of the mutual savings banks have wide discretionary powers of management. The laws of the various states broadly outline the types of investment which the banks may make and give the trustees great latitude in making the investments. Dividend rates are fixed on a basis of earnings and are neither guaranteed nor determined in advance. Annual losses or profits are divided ratably among depositors and are not absorbed by the government. There is no government guarantee to repay deposits—except as provided for under the federal insurance (voluntary for mutuals) and the state (Connecticut, Massachusetts and New Hampshire) guaranty plans, to which the banks must contribute.

The post office savings bank system of the British Isles was established in 1861. The immediate reasons for the creation of a government owned and operated savings bank system were the weaknesses of the trustee savings bank system. At the present time the two systems are identical in all major respects except that the postal savings system does not operate the Special Investment Department. In terms of the number of accounts (approximately 20 millions) and amounts on deposit (approximately £2 billions), the postal savings system is the most important savings bank system in the British Isles. Joint stock banks began to accept savings deposits about 1904 and have become serious competitors of the trustee and post office savings bank. During World War I, the city of Birmingham started a municipal savings bank which was reorganized in 1919 and is quite successful. The author also discusses the savings banks established for the very poor; for school children; and for persons in the merchant marine, army and navy.

The savings banks of the British Isles played contrasting roles in financing

the two World Wars. They were unimportant in World War I because the government borrowed funds at interest rates ranging from 4 to 6 per cent through the sale of small denomination bonds. Although the funds of the savings banks were also used to finance the war, the government refused to increase the 2.5 per cent interest rate paid the depositors. Between the wars interest rates declined and during World War II the government was able to borrow funds at approximately 3 per cent. Although the rate of interest paid savings bank depositors remained at 2.5 per cent, the difference was not great and the ability to withdraw on demand was an advantage. Under these conditions, the trustee and post office savings bank systems contributed approximately 50 per cent (£1.400 millions) of the "small savings" used in financing World War II.

Over one-half of the text deals with the period prior to 1866. Since there are at least two excellent histories on savings banks of the British Isles covering this period,² the author might have placed greater emphasis on the period since 1866. There is no analysis of the part, if any, played by public or private borrowers in the origin and development of savings banks. The volume contains materials which are not germane to the main theme. A case in point is Chapter XI which is devoted to the proposal, advanced between 1850 and 1870, that ownership of a savings account be made a suffrage qualification. While the discussion is interesting, a paragraph would have been sufficient, especially since the proposal did not become law. The author draws from many sources but does not give the dates or pages of the citations. The index is poor; the bibliography excellent. Taken as a whole, the volume is extremely worth while and is recommended reading, especially to students of finance and history.

DONALD SHAM

Washington, D. C.

Recent Banking Developments. By SAROJ KUMAR BASU. 2nd ed. (Calcutta: The Book Exchange. 1947. Pp. ix, 382. Rs. 12/8.)

The first edition of this book, by a University lecturer in economics at Calcutta, was published in 1946. The second section "has been thoroughly revised and brought up to date," and a new section of over fifty pages on Post-War Machinery For International Monetary Co-operation has been added. The book is a world-wide survey of the main trends in banking, and in particular central banking, since 1929, with special emphasis on the Indian situation. The author's comment (p. iv) on the "entire non-existence of relevant statistics" in India that "are readily available for other countries" would support the general impression among American economists that economic statistics for most of the Middle Eastern countries are very limited.

Business Finance; Investments and Security Markets; Insurance

Business Organization and Finance. By HOMER V. CHERRINGTON. (New York: Ronald Press. 1948. Pp. vii, 485. \$4.50.)

In the words of the author, this volume "is addressed to college students. It is intended to serve as a basic text in business organization and finance." It should therefore be appraised from the viewpoint of its adequacy and suitability for college classroom use.

In the opinion of this reviewer, Professor Cherrington has produced an excellent text. The book covers the subject adequately; it is exceptionally well organized; and it is simply and clearly written. Twelve types of business organization are discussed, ranging from individual proprietorships to mergers and consolidations. In addition, separate chapters are devoted to "Cooperatives" and "Government Corporations." The discussion of each type of business organization follows an unusually uniform pattern, treating in sequence the following topics: legal nature, ownership, leadership, finance, principal advantages and disadvantages. Of these topics, the treatment of "leadership" opportunities in the various types of business organization is somewhat unique. Throughout the book, public policy is stressed by brief digests of significant statutes and frequent references to important court decisions and administrative rulings. The condensation of this portion of the text material is uniformly good, the chapter on "Federal Regulation of Securities Markets" being especially well done. The treatment of controversial topics such as competitive bidding for corporate securities is fair and unbiased, both sides of the argument being presented with a minimum of indulgence in personal opinions.

The weaknesses of the book are those which would be expected to be found in any text written for use in a standard college course. So many texts have been written in the field of business organization and corporation finance that it is difficult, if not impossible, to present significant new material. The documentation throughout the book indicates clearly that Professor Cherrington has drawn heavily on his predecessors. Moreover, the very factors which render a volume excellent as a textbook—careful organization and simple diction—tend to make the book rather dull and monotonous to the non-student reader. The inclusion of up-to-date illustrative material tends to offset these inevitable disadvantages, and more such material would have enlivened the text, although it is recognized that space limitations were to be considered. A large portion of the illustrations actually presented appear in the fine print of footnotes, and too many of the cases date back to the first quarter of the century.

Nevertheless, Professor Cherrington is to be congratulated on achieving his objective. He started out to write a textbook for a standard college course and he has produced a worthy competitor in a crowded field.

The University of Texas

Public Finance

Public Finance. By URSULA K. HICKS. (Cambridge: University Press. New York: Pitman Pub. Corp. 1947. Pp. 392. \$2.50.)

This new study of public finance should prove to be a welcome addition to the list of texts already available. Not only does it present the old things satisfactorily; but also, unlike most texts, it contains original and useful contributions. Many teachers of public finance will, I believe, find that it comes close to what they want for their students, and all of them will discover in it ideas and relationships that will stimulate their teaching and research. This volume helps to maintain the high standard set by the Cambridge Economic Handbooks, and when one recalls the others in the series—Robertson's "Money," Robinson's "Monopoly," Harrod's "International Trade," and the rest—this will be taken as high praise.

The book is analytical rather than descriptive, though in the first part—about 30 per cent of the total—the author sets out the main characteristics of the British revenue and expenditure machinery. The desirability of familiarizing the student with administrative processes is, I believe, obvious. There may, however, be some question about the advisability of including so much historical material. One wonders whether, in a volume that must be kept so short, space to consider the history of the Budget message, and of the consolidation of the Budget accounts (to name only two points covered historically) represents an optimal use of pages. Naturally, there is little about the fiscal institutions of other countries. But it is possible that the rather general remarks about American administrative machinery, introduced mainly to provide a contrast with the British, will be enough. Incidentally, is it not an error to account for the lighter over-all tax liability of the American citizen (compared to the British) as "partly due to the greater wealth of the United States, calling for lower rates of taxes to get the same per capita revenue" (p. 88)? Though greater wealth per capita in the United States would require a lower tax rate on each dollar of wealth or income to raise the same per capita revenue, it would not explain a lower rate of tax liability for each citizen (£22.2 as against £26 in the United Kingdom).

It is in the second and third parts that the author makes her real contribution. She divides her analysis into two sections; first, a consideration of the partial effects of taxes (and expenditures), and second, a consideration of the general or income effects. The analysis of the partial effects, presented in Part II, covers something of the same ground as, but goes well beyond, conventional tax incidence theory. The analysis of the general or income effects (Part III), familiar to us as fiscal policy, is now back where it belongs as a part of public finance.

The novelty and importance of this analysis of tax incidence (the theory of taxation) consists in the fact that it is concerned with a different kind of question than the one generally asked. Whereas the analyst has usually been interested in discovering who pays the tax, the landlord or the tenant, the cigarette smoker, the cigarette manufacturer, or the tobacco grower, Mrs.

Hicks asks a more purposeful set of questions; what factors influence the size of the price increase resulting from a higher tax and (more important), what are the consequences of the increased price (or reduced income) upon taxpayers who will alter their consumption patterns, and upon producers who will have to reallocate factors? Here she makes use of criteria and principles developed in the study of welfare economics—the production and utility optima, producers' and consumers' surplus, and so on. The loss of surplus for different kinds of taxes, and their distributional effects are compared. And though it seems unduly optimistic to hold that "the production and utility optima in the form just stated are capable of being brought into relation with statistical and econometric enquiries, and so are capable of becoming practical directives of policy"; at least, stating the criteria as to the choice of policy in this way ensures that the right kind of considerations will enter into policy determination.

The analysis of the use of taxation and expenditure policy as a method of ensuring a full use of resources (one of the necessary conditions for the satisfaction of the production criteria) is conventional. The effect of taxes on the propensity to consume and investment is considered. Likewise, the income-generating effect of public expenditures is taken into account. The monetary implications of a budget deficit are also considered. However, it is perhaps surprising that she devotes not much more than a third of the space given to tax incidence to these problems of maintaining income. Are these matters now so obvious that little needs to be said?

Certain lapses in exposition must be mentioned. It would be easier for the student to see the importance of the policy criteria set out if they were used explicitly in the analysis of the various taxes considered, and if their relation to effective incidence were developed in greater detail. There is an appearance (though it does not exist in reality) of a lack of integration between the material in Chapter 7 (which sets out the criteria to be used) and the rest of the book, which could have been avoided. Also, though the style is acceptable, it is not as clear as it might be. Nevertheless, the author has made an important contribution, and many will derive profit from studying it.

LORIE TARSHIS

Stanford University

National Debt Series. By Committee on Public Debt Policy. (New York: Committee on Public Debt Policy. 1946-48. Nos. 1-7.)

The seven reports of this series, published over a period of two years, are sponsored by a committee of economists, and bank, insurance and manufacturing officials. The chairman of the committee is W. Randolph Burgess and the director of research is Professor James J. O'Leary. The reports cover the history of American war debts (No. 1), and the debt in relation to the banks (No. 2), insurance companies (No. 6), interest rates (No. 3), the budget (No. 4), and savings (No. 5). The final report (No. 7) summarizes the earlier studies and their recommendations.

The series does not offer new material in this field. It is designed, rather, to present a point of view. The stated aim of the studies is to assist in deter-

mining that policy of debt management which "will be the best for the welfare of our people and the strength and financial stability of our Government." But it is assumed—in advance of inquiry—that such a policy "must seek these ends through utilizing and encouraging the individual ambitions and creative energies of our people" (No. 1, pp. iii-iv). This is, perhaps, not a serious limitation on inquiry, but it would have been more convincing if it had appeared as a conclusion rather than a premise.

Those seeking further light on the problems of debt management will not find it here. The final recommendations are to reduce government expenditures, to reduce the debt, to transfer debt holdings from banks to other investors, to permit flexible (*i.e.*, higher) interest rates, and to reduce taxes. These points are clear, but too general to serve as a guide since rising interest rates increase government costs, and reduced taxes decrease the possibility of debt reduction. Any practical program of debt management must give some clue as to priorities or indicate the desirable proportions in which these conflicting measures should be realized. The authors of individual reports sometimes indicate preferences, but there is no complete agreement among them, and the final report makes no clear-cut choice.

Probably no one would quarrel with the desirability of transferring debt holdings from the banks to other investors, but this is to be achieved, apparently, by offering the other investors higher interest rates. No estimate is given as to how high interest rates might have to rise to attain this end, nor as to what proportion of the public debt must be refunded at these higher rates in the next few years. Yet these are important factors in determining government expenditures. Interest on the debt, even at 2 per cent, is a substantial item in current budgets. Nor is there any clear guide to the appropriate rate of debt reduction. In the fourth report, it is suggested that \$30 to \$40 billions might be paid off in the next decade, and the author gives moderate debt reduction priority over tax reduction. However, the final report makes no such choice. Apparently government expenditures, other than interest, are to be reduced enough to provide for tax reduction, debt reduction, and higher interest rates as well.

The series is, in the judgment of the reviewer, open to criticism on another count: the failure to state clearly the assumptions underlying the recommendations. In none of the reports can there be found any real discussion of the relation of the government budget to the national income. In view of present controversies in this field, any study of the national debt that does not state specifically the principles on which its conclusions are based will have limited value. Only the fifth report, on the national debt and savings, gives much consideration to this problem. This report stresses the importance of encouraging savings, apparently on the assumption (never specifically stated) that investment is limited by the amount of savings individuals and corporations decide to make. Moreover, it appears to credit improved standards of living in the past solely to saving. No mention is made either of capital-saving inventions, or of attempts to save that have failed to be translated into new investment. Our fiscal and monetary policy is indicted on the charge of having checked savings. But there is no convincing proof. (See,

especially, No. 5.) It is implied that a reduction in government spending would check inflation without reducing business activity and that a reduction in taxes would increase business activity. All this is possible, but the qualifications that might make this position tenable are lacking.

There is still much to be learned with respect to national debt management. Guidance is badly needed. It is all the more to be regretted, therefore, that the money and talent invested in this series of reports were not used to explore practices in other countries, our own past experience, some of the recent theoretical developments, or in other ways to increase knowledge in this field.

International Economics

The West at Bay. By BARBARA WARD. (New York: W. W. Norton & Co. 1948. Pp. viii, 288. \$3.50.)

The West at Bay is a tract for the times—an eloquent, persuasive, and often inspiring brief in support of closer association among the nations of Western Europe. It is Miss Ward's essential thesis that the nineteenth century political and economic order has vanished, that Western Europe's international economic crisis is not merely a passing consequence of World War II but rather the war-accelerated resultant of a far older and more deep-seated trend, and that lasting economic recovery and preservation of Western Europe as a continuing fountainhead of the cultural values of western civilization can be obtained only through far-reaching political and economic integration.

After introducing her argument in summary form, Miss Ward reviews in two sections of the book the political, social, and economic elements in the gradual decline of Western Europe's position in world affairs and the corresponding rise of the United States. She then sketches the immediate background of the inception of the European Recovery Program, stressing the relation to closer western association and the failure of the projections made in the fall of 1947, either by the Committee for European Economic Cooperation or by the U. S. government, to show a balance in Europe's dollar accounts by the close of the four-year period.

It may be noted parenthetically that Miss Ward pays far more serious attention to the official American long-range projections than would the authors of those estimates. She also appears to confuse the deficit in 1951-52, when the program would, according to the original plan, be in its final year, with the possible situation thereafter. Her essential point, however, namely the formidable difficulty in foreseeing a dollar balance by 1952 without either a drastic shift in the terms of trade in Europe's favor, a considerable and perhaps politically intolerable reduction in European consumption, or a far larger flow of private investment funds than appears likely, seems to be borne out by the preliminary survey of the EKP countries' four-year programs undertaken at the end of 1948 by the Organization for European Economic Cooperation in Paris.

In the concluding section of the book, entitled "Western Association,"

which occupies about one-third of the whole, Miss Ward sets forth her plea for closer association and a series of specific proposals for immediate steps on the economic side.

The book reflects those literary and intellectual qualities which were to be expected from its authorship by the young and brilliant foreign affairs editor of the London *Economist*. If not pretending to profound scholarship, the work represents informed journalism at its very best. It is well written. It evinces an excellent historical sense. Miss Ward deals competently with economic issues, although the book is not directed primarily at economists and the professional reader will find some of the exposition (notably the summary of Keynesian trade cycle analysis) oversimplified beyond recognition. Above all, Miss Ward displays a profound understanding of and abiding faith in the fundamental cultural, human, and moral values developed by the liberal and humane tradition of Western European civilization and a recognition that without genuine recovery in Western Europe its vitality as a continuing source of cultural development may well be stifled.

The most striking feature of *The West at Bay* is its attempt to come to grips on a step-by-step basis with the process of achieving closer Western European association, especially on the economic side. The discussion is introduced by a brief chapter on regional defense, which is essentially an advocacy of the type of arrangements now being created under the Brussels agreements. On the political side, Miss Ward decries constitution-writing at the present stage as mere blueprinting of "Never-Never Land," although she fully recognizes the indissoluble linkage of economic with political factors. She endorses as a first political step a regularized conference of Western European prime ministers, using the Brussels defense organization and the Organization for European Economic Cooperation as a permanent secretariat, leaving for the future more ambitious experiments in federation. In her own words (p. 196), she is "primarily concerned with the concrete questions of strategic and economic cooperation, not because they are substitutes for political decision, but because they are the difficult tests by which the genuineness of the nations' political will is to be judged."

Miss Ward's program for Western European economic association comprises four elements: (a) OEEC allocation of basic materials and equipment on criteria of optimum region-wide use, to be followed by federation of the coal, petroleum, steel, transportation, and power industries into international public corporations, paralleled by an international agricultural planning agency; (b) development of an international capital planning board to guide (and perhaps control) the rate and direction of capital expenditures both in the internationalized industries and in major private industries; (c) gradual movement toward reduction of barriers to intra-European trade and migration, with special emphasis on what amounts to a regional currency union; and (d) a concerted region-wide attack on the dollar shortage, including a planned sharing of austerity in dollar imports, joint development of non-dollar sources for food and raw materials, and a concerted sales effort for exports to the dollar area.

It should be said at once that Miss Ward's program raises at least as many questions as it answers. It is simply taken for granted, for example, that

rationalization of basic industries under coordinated international control would achieve real economies. There is no reference to possible diseconomies of large-scale administration by an international bureaucracy. Perhaps there are sound *a priori* grounds for believing that international horizontal integration may afford greater economies than horizontal integration within national boundaries, since competitive nationalist development of basic industries in small countries clearly entails serious economic disadvantages. On the other hand, as Miss Ward herself recognizes, the very pressures of economic nationalism are the most formidable obstacles to achievement of such a program. Nor does the supporting evidence of the postwar European international allocating agencies appear genuinely relevant. The European coal, transport, and associated organizations now combined into the Economic Commission for Europe were engaged primarily in avoiding excessive distortions in the distribution patterns of acutely scarce materials in the immediate postwar years, and have barely scratched the surface of region-wide rationalization. Again, Miss Ward omits anything more than casual reference to problems of inflation, exchange rates, and discrimination against dollar imports—matters essential to a comprehensive discussion of the broad issues raised by the book as a whole.

Indeed, the reader is left with a puzzled sense that, while Miss Ward has put forward Western Europe's apparent inability otherwise to achieve international viability at a tolerable living standard as the principal argument for closer association, she has provided little evidence that her specific program would make a major contribution to international economic balance. It is no doubt probable that it would help. In any event, the strategic and political advantages of strengthening Western Europe through closer association are so clear-cut that Europeans would be well persuaded to develop closer economic cooperation, if only as an act of faith. Miss Ward's greatest contribution, however, lies in asking many of the right questions and in making an all too rare attack on the central operational problems of precisely where and how to start effecting a lasting solution to the strategic, political, and economic issues which beset Western Europe. She has placed the economic problem in its proper perspective in relation to political and moral factors. It is with this perspective and in response to these questions that the further spade work of finding constructive answers must be pursued, both by Europeans and by Americans in their role as participants, providers of aid, and in the long-run beneficiaries of the European effort to preserve the western heritage.

LINCOLN GORDON

Harvard University

A Second Review of *The West at Bay*.

Said Mr. Wrigley to Mr. Ford

"Chew more of my gum or, on my Ward,

I never can buy another Lincoln;

My balance with you is persistently sinkin'".

Said Mr. Ford to Mr. Wrigley
 "You're cuckoo, my boy, not to say higgly-piggly,
 Our reciprocal sales may be far from mates,
 But the rest of the world still masticates!"

Anon.

These quatrains are cited more in desperation than in mirth. I am in complete sympathy with Miss Ward's general ideals and have no doubt that she merits many of the encomiums showered on her by her publishers and somewhat naïve reviewers. But if it is true, as the jacket of this book quotes John Fischer as saying, that Miss Ward is "probably the most brilliant writer on economics . . . in all of Europe," then the West is not only at bay but practically certain of irrevocable *Niedergang*.

The book professes to demonstrate the urgent need of a centrally planned (but, of course, not "authoritarian") economy for Western Europe as a means not only of combatting the centrally planned (and, to its protagonists, profoundly "democratic") economy and politics of Europe's eastern sector, but also of competing with the overweening American Colossus. Miss Ward is deeply concerned about "balance," and, among other errors, thoroughly confuses the balance of power with the balance of payments. Despite her disesteem of Russia, she swallows whole, and regurgitates, the Soviet doctrine that the American policy of liberalization of international trade would be fatal to countries with "weaker" industries than those of the United States, and, while professing the contrary, she is obsessed with the philosophy of bilateralism.

The jacket states that Miss Ward took first class honors in economics at Oxford University, and presumably, therefore, has heard of the doctrine of comparative advantage. There is, however, not the slightest evidence that she knows what it means. She is therefore unaware that *per capita* productivity (or national poverty) has nothing whatever to do with *balance* in international trade (unless, indeed, it should be alleged that unalleviated poverty would *ensure* it), or with national competitive capacity. She even convicts herself out of her own mouth since she cites, among the long-run historical causes of Britain's present economic difficulties, the British loss of markets to Japan (where *per capita* productivity was never anything like as high as that in Miss Ward's homeland) as well as to the United States (where it has long been higher.) If Britain lost in competition with the United States because American industry was strong (in Miss Ward's sense), why did Britain also lose in competition with the Japanese where industry, by the same criterion, was weak? Miss Ward cannot be right on both counts, though it is possible, and is, in fact, the case, that in both she is, in her inferences, profoundly wrong.

Miss Ward, further, is much impressed with mere size as a factor in competitive power. This is sometimes presented as the size of the firm, and sometimes as the size of the market. It is, however, notorious that large firms, such as General Motors, are mortally afraid of the inefficiencies of great size; that, for this reason, they decentralize their operations, knowing

that only the most strenuous efforts to combat hardening of the arteries keeps the concern abreast of certain of its much smaller competitors. It may, moreover, not be out of place to call to Miss Ward's attention the principle of opportunity cost which would tend to calm her fears of size even if they were otherwise justified. For, if the United States has a comparative advantage, and specializes, in the industries where the greatest size is all-important it must, *pro tanto*, abandon those industries where the greatest size is less significant. One cannot *specialize* in the output of anything without reducing the output of other things below the level that would be necessary to meet even the reduced (total) demand under conditions of self-sufficiency. Other countries will then come in to supply this gap in demand. There are, moreover, very few industries in which the British home market could not be large enough to give any feasible economies of size.

Miss Ward labors *ad nauseam* the point of the long-run shift of political power from western Europe to other parts of the world, and seems to think that this is highly important economically. Yet similar shifts of political power have been in process since the beginning of time without corresponding economic consequences. Sweden, Denmark, Holland, and Switzerland have, to take a modern instance, been losing in relative political might much longer than western Europe as a whole, but have, nevertheless, rather steadily improved their economic status. The United States itself, moreover, did quite well economically when its international political power was small (relatively better, in fact, than after it had become a major political power.)

Miss Ward is further convinced that western Europe cannot function satisfactorily except as an economic unit. If this were true, the obvious recourse would be to intra-west-European free trade. But Miss Ward dismisses all this as of less than nugatory value. Since such free trade would surely result in a great deal more complete economic integration than would any other conceivable policy, its practically unconsidered rejection means that Miss Ward will have west-European economic integration only on her own terms, *i.e.*, "planned" under the British aegis, or, at least, with a very lively regard for specific British interests. She wants *national* planning *within* a European union. This is surely a prescription for conflict or for chaos.

The "dollar crisis," discussed in the Introduction, is now (and, perhaps, always was) solely a matter of discrepancy between the controlled external (exchange) value of the pound sterling, and other European currencies, and their (lower) internal values. For reasons which it is impossible here to detail this is leading not only to the "dollar shortage" but to a monstrous distortion of trade. Miss Ward presumes to lecture Americans on their economic illiteracy and suggests (truly) that it will be very difficult to make the American cotton or tobacco grower understand why the dollars he has voted in Marshall plan aid should be spent on non-American tobacco or cotton at higher prices than those at which he himself is eager to supply at least equally good products. It is, of course, all but certain that I share what Miss Ward conceives to be the general economic illiteracy of my compatriots, but I submit that it would be difficult to make *any* intelligent person under-

stand why such a thing should be done, and I would say that, if Miss Ward thinks she knows the reason, she had better look to her own economic education than to that of the American people at large.

The truth is that there may be a case for paying apparently high prices in *sham-money*, valued against real money at factitious rates of exchange, than for paying the same, or somewhat lower, prices for the same goods in any real money (dollars or other "hard" currencies). The difference between the two ostensible monies is that the sham-money is useful only in the purchase of goods with which the supplier of the money wishes to dispense, while the real money (as *must* be the case if it is to be real) may, at the will of the possessor, be used to buy anything at all. The sham-money is, of course, not worth in real money what the authorities declare it to be worth, and even the illiterate American cotton or tobacco grower might understand that it might be worth while to offer to a seller of goods a somewhat larger amount of this stage money than to pay him an equivalent face value of dollars, or any other real, even if far from ideal, currency. But his (doubtless naïve) reaction might be to ask why governments should insist on putting a sham exchange value on their monetary issues and thus make internationally quoted prices a hopelessly inept, when they could be an all but perfect, allocator of resources. (Nor is the answer to this query quite what Miss Ward might think it to be.)

Miss Ward's "economics," in short, is in the tradition of Hjalmar Schacht, Thomas Balogh, and the bullionists. This may, perhaps, be the (resurgent) wave of the future, but it has not yet established its position in a still partly rational world, and some of us, in the United States at least, are still so conservatively unregenerate as not to have lost all faith in hardheaded rationality. We would prescribe for Miss Ward another journey to Pieria and a good long draft of its waters.

This review is consciously harsh. There are many nice things that might be said about Miss Ward though it would, in this respect, be extraordinarily difficult to compete with the publisher's blurbs. It must be said, however, that she writes most engagingly, that her heart is in the right place, and that, when she does not get beyond her depth, she swims very prettily indeed. She is all too plausible. I am led to blunt speaking, however, by the conviction that these qualities are doing all but irreparable damage to the cause of freedom, for which Miss Ward, I am sure, feels a warm affection. She builds a structure which, completed, she would abhor; and, though written in all innocence, this is, to a libertarian, a subtly dangerous and a highly subversive book.

FRANK D. GRAHAM

Princeton University

The Economic Reconstruction of Europe. By GEOFFREY CROWTHER. Foreword by Homer D. Crotty. (Claremont, Calif.: Claremont College. 1948. Pp. xii, 79. \$2.75.)

In this volume, the associated colleges at Claremont, California, have made

available the text of three lectures delivered under their auspices at the end of February, 1948, by Geoffrey Crowther, editor of the London *Economist*, under the respective titles, "The Vitality of Europe," "Freedom and Order in Europe," and "America and Europe." The lectures are pitched at the level of the intelligent but not overly informed layman, and make no pretense at professional economic analysis of the issues. They are in part outdated by subsequent events. But they repay reading by virtue of that beautifully lucid style which graces the pages of the *Economist* under Mr. Crowther's editorial supervision, and the many provocative reflections which often make one eager for further development of the author's views.

The essence of the first two lectures is summarized by the author himself in seven points (pp. 61-64), which may be briefly paraphrased: (1) In comparison with the time required for recovery after other wars, the continued existence of major economic dislocations in Europe is neither surprising nor particularly significant; (2) The war-induced changes in Europe's economic position are mostly temporary, the permanent ones (notably liquidation of overseas investments) being comparatively unimportant; (3) The chief sources of Europe's present economic troubles may be eliminated fairly promptly, especially through a major reversal of the terms of trade in favor of Europe as an industrial exporter; (4) The East-West division of Europe, while of enormous political importance, is not of great economic significance; (5) Germany is a major exception to point 4 and is Europe's most difficult economic problem, which can be satisfactorily resolved only through economic reconstruction and political integration within a larger European association; (6) The socialist trend in European economic policy is not as extensive or as doctrinaire as is commonly thought in the United States, is largely a response to limitations of the European environment, and will not greatly affect the prospects for successful European reconstruction; and (7) Western European federation is neither a prerequisite to economic recovery nor particularly desirable from a merely economic viewpoint, but is highly desirable politically and should be promoted by the United States under the opportunity afforded by the European Recovery Program. In his third lecture, Mr. Crowther warns against unduly restrictive conditions on American aid under the European Recovery Program and finally, looking to the longer-term picture, calls for continuing American leadership in a community of nations spanning the Atlantic Ocean.

From the lectures as a whole, two points of major interest stand out. The first is Mr. Crowther's striking optimism as to the comparative ease (except for Germany) of obtaining a balance in Europe's international accounts and his expectation that the British problem will be solved largely through a restoration of more favorable terms of trade with primary-producing countries. Mr. Crowther appears to assume that 1938 is an adequate standard for judging the problem of European recovery. This view contrasts sharply with Barbara Ward's conclusion (*The West at Bay*, 1948) that the postwar dislocations are a magnification and acceleration of a serious relative decline in the Western European economy which began well before the first World War. In this reviewer's judgment, Miss Ward rests on sounder ground. In view of the increasing economic self-consciousness of the primary-producing coun-

tries, it is difficult to believe that terms of trade such as those of the mid-'thirties will recur and be maintained over considerable periods of time. The British have accomplished wonders in reducing their dollar deficit from \$2.7 billion in 1947 to a prospective \$1.3 billion in 1948-49, but these gains have been made in a seller's market for industrial goods and in the total absence of German competition. It is difficult to see how any prospective improvement in the terms of trade can remove more than one-third to one-half of the remaining deficit. In any event, the March, 1948, Report of the Economic Commission for Europe suggests that for Western Europe as a whole, in contrast with Britain, the terms of trade have not substantially deteriorated in relation to prewar. International economic viability at tolerable living standards for the entire area would appear to necessitate substantial structural modifications in the western European economy to achieve reduced dependence on imports and increased productivity. At least some of these changes would be greatly fostered by closer economic integration.

On the political side, Mr. Crowther's lectures remain particularly timely. Although less insistently than Miss Ward, and with far less emphasis on economic measures, he also calls for closer western European union, particularly of the five Brussels powers and possibly Denmark and Norway. He would begin with the pooling of military forces, both for its own sake and on the ground that without pooled defense, planned economic specialization is unacceptable. He suggests, for example, that lack of military integration would prevent the British from accepting a French monopoly of watch and clock making (precision instruments in wartime) and would prevent the French from accepting a British monopoly of tractors (tanks in wartime). One may doubt the force of this particular argument, since even within a militarily and politically united Europe the geographically less vulnerable areas would have a strong claim for the location of all strategic industries. Would not Portugal, Eire, Iceland, and Norway be the real beneficiaries of such a policy?

Granting the priority of military union, one is also tantalized by the need for more specific delineation of the remaining possible successive stages toward political and economic integration. The technique of military pooling is a relatively simple matter. The great gap in today's thinking lies between this vitally important but conceptually simple stage and the starry constitution writing of the World Federalists, Union Nowers, and Atlantic Community makers. Mr. Crowther in the instant volume just begins to shed light on this matter. It is devoutly to be hoped that it may soon be further illuminated by his almost unique combination of political and economic wisdom on western European affairs.

LINCOLN GORDON

Harvard University

The European Recovery Program. By SEYMOUR E. HARRIS. (Cambridge: Harvard University Press. 1948. Pp. xvii, 309. \$4.50.)

"The object of this book," Professor Harris writes, "is not only to explain

the ERP and the major issues involved; but also to offer some points for consideration when the legislation is again reviewed early in 1949 and later years."

The organization of the book is designed to meet the requirements of the hasty reader. The first twenty pages contain brief statements about the major issues raised by the European Recovery Program and present summary conclusions. Part One, about sixty pages, is given over to an elaboration of the major issues and the rest of the book is largely concerned with the basic data and related estimates and explanatory materials which were submitted to the Congress during the first quarter of 1948. The points which Professor Harris offers "for consideration when the legislation is again reviewed" are interspersed throughout the text and are not always clearly definable.

Professor Harris isolates about eight major issues involved in the formulation and administration of the Program. He believes that the outcome of these issues will largely determine the extent to which the European participating countries by the end of 1952 will be able to support themselves at high levels of economic activity and at tolerable standards of living. On almost every one of these problems the author comes to definite conclusions which are presented in the earlier sections of the book, designed for reading by busy officials and executives. Discussion and qualification appear in the sections which the "general reader and student unhurried" might read (p. x).

Three of the problems which Professor Harris believes will influence the success of the Program relate directly to domestic economic policies. In his opinion, the United States has thus far failed to adopt the necessary controls on inflation. Furthermore, Professor Harris fears that the Program might degenerate into a subsidy system for American producers. He also questions the desirability, in view of the alleged costs involved, of using ERP to support private American enterprise. The author asserts that utilization of private channels of trade for procurement of goods financed by the Economic Cooperation Administration "may cost the taxpayer billions of dollars" (p. 15). Although he recommends centralized government procurement "of all supplies required under the ERP," Professor Harris does not explain how such an agency could effect economies in the purchase of thousands of commodities and he fails to consider the effects of such a policy on the future of private enterprise in international markets.

The author observes that the extent of communist opposition will affect both the outcome of the Program and the amount of supplementary military aid which might be provided to certain countries. With respect to the non-communist countries which are not participating directly in the ERP, Professor Harris believes that the Executive Branch arbitrarily reduced the estimated cost of the Program to the United States Treasury by placing excessive burdens on the other countries in the Western Hemisphere. He states that these countries "are being asked to provide goods under the ERP in exchange for credits or dollars; and the use of these dollars is to be subject to control by the United States" (p. 16). This judgment does not deter Professor Harris from urging the adoption of an effective system of export

commodity controls which would divert United States exports to Europe "at the expense of other areas" (pp. 198-201).

The author notes that United States assistance is extended on condition that "approved" policies are carried out by the participating countries. Professor Harris believes that United States authorities are pursuing erroneous policies in certain important areas. For example, United States executive branch officials are making "strong statements" in favor of foreign exchange rate devaluations. At the same time, they are dodging the issues about controls of resources and even of wages and prices in Europe since a stand on those matters might provoke embarrassing controversy about U. S. domestic policies. On the question of exchange rate devaluation, Professor Harris seems to me to be attacking a windmill of his own making. A careful examination of the Congressional hearings did not yield statements which would support his charge. The author refers to, but does not cite in his references, certain statements made by the National Advisory Council on International Monetary and Financial Problems. I believe I have located the proper document and the strongest statement found therein is mild indeed, even when quoted out of context. "The Council . . . believes that some adjustments in exchange rates (of member countries of the International Monetary Fund) may have to be made in the near future." The next sentence in the text adds significant qualifications. "Any action in Europe must, however, be related to the provision of American assistance under the European recovery program and in all instances must also be related to the steps taken toward the internal stabilization of the economic and financial situations of the member countries."¹

The author believes that the Executive Branch pressed too hard for deflation of investment programs of the European countries and therefore the cost to the American taxpayer for the "next ten to twenty years" might be substantially greater than present estimates. Furthermore, other considerations lead the author to doubt that the European countries will become independent of extraordinary outside assistance by the end of 1952. "Even if the desired rise of output is achieved, however, there will remain serious obstacles to wiping out the major part of the deficit in the balance of payments, and in particular with the United States. Here is the most perplexing problem of all, and it may well not be substantially solved in four or five years, even if the ERP is favored by rising productivity and output and correct fiscal and monetary policies" (p. 25). As an adherent to the thesis that persistent dollar shortages will continue in world trade, Professor Harris is almost forced to take a dim view of the prospects for recovery in Europe. Since the thesis of dollar shortages tends to discourage strong efforts on the part of countries to increase exports, particularly exports to the hard currency areas, it is difficult to accept this view and also the author's belief that an enlarged investment program in the European countries would contribute materially to a solution of their dollar-deficit problem.

¹ *First Special Report of the National Advisory Council on the Operations and Policies of the International Monetary Fund and the International Bank for Reconstruction and Development*. 80th Congress, 2nd Sess., H. D. No. 656 (May 18, 1948), p. 12.

The controversial nature of the author's conclusions on many issues raised by the European Recovery Program should not obscure the fact that Professor Harris has highlighted some of the basic problems involved in this vast undertaking and that he has presented to students of the subject the relevant factual materials from which independent conclusions can be derived.

W. H. BRAY

Washington, D.C.

Business Administration

Advertising and Economic Theory. By E. A. LEVER. (London, New York, and Toronto: Oxford Univ. Press. 1947. Pp. xi, 132. \$2.75.)

This tiny book (it would cover only 65 pages like this one) was written, its preface explains, "primarily to invite young economists to think out the proper place of advertising in economics and to emphasize the necessity for a theory of consumption," and secondarily "to suggest a method of bridging [the] gap as far as advertising is concerned" between "practical men of affairs, [who] appear generally to think that economic theory is intellectually inaccessible," and "theoretical economists, [who] are often severe in their strictures on what appears to them to be the naïve and amateurish language of the practical men."

The main argument of the book is summarized in the final chapter as follows: "The marketing of consumption goods is subject largely to conditions which are variously called imperfect, monopolistic or non-price competition. . . . Advertising provides a tool which gives prospects of profitable consumer demand. There is probably little or no restriction of outputs to maximize profits, as is asserted in the theory of pure monopoly; indeed, within wide limits, producers generally wish to increase their outputs up to their respective optima or, in ignorance, often beyond these optima. Costs are incurred in this attempted growth and frequently a substantial part of advertising costs can be looked upon as growth costs." The following points are listed as tentative conclusions "which must be taken care of in a realistic economic theory": (1) "A manufacturer of consumption goods cannot obtain the benefits of mass production without using advertising. Low—or lower—prices are less frequently a sufficient inducement to buyers than is assumed in the elementary economic theory of supply and demand." (2) Advertising produces utility by creating wants which are then satisfied. (3) Advertising can, under some circumstances, result in gains of efficiency sufficient to offset its own costs; and while it may sometimes cause waste, such waste is a consequence not of advertising but of freedom of consumer choice. (4) "The distinction . . . between 'informative' and 'combative' advertising is not realistic. In any case, . . . the greater proportion was informative." (5) "Advertising tended to be correlated with production rather than *vice versa*." (6) "Advertising can be a form of Investment, in Lord Keynes' use of the term."

Needless to say, not all of these conclusions can be fully substantiated in

a book of this size. A good many propositions, especially those relating to economic theory, are supported only by quotation marks and references to recognized authorities, most frequently Borden, Chamberlin, and Robinson. Indeed, Lever is, on the whole, surprisingly uncritical of both economic theory and advertising.

If the book has a particular merit, it is that it touches a good many of the economic issues that have been raised concerning advertising, mentions the principal literature, and presents some institutional and statistical data on advertising. Thus, it may prove, as the author intended, of some value to a "young economist" someday mapping a more thorough and penetrating investigation of the role of advertising in the economy. Such an investigation should, for one thing, examine existing theories of imperfect and monopolistic competition with regard to the consistency of their conclusions with actual advertising practices—with regard, that is, to the ability of these theories to organize, predict, or rationalize observed advertising practices.

Industrial Organization and Markets; Public Regulation of Business

Problems in Price Control: Pricing Techniques. By ROBERT J. BENES, REED DICKERSON, JOHN A. HART, DAVID KASS, A. MOORE LIFTER, and JOHN W. PASCHKE. (Washington: Supt. Docs. 1947. Pp. xi, 286. 55 cents.)

This volume, the eighth in the series of general publications dealing with the work of the Office of Price Administration, consists of six essays, each called a chapter. The whole is designed to give an exposition of certain price-fixing techniques used by the agency during the war period and immediately thereafter. The approach is roughly historical, beginning with the first of the general techniques used after the agency had the direct statutory authority of the Emergency Price Control Act of 1941. This was the General Maximum Price Regulation, and is described by John A. Hart in the first chapter. The following chapter, written by Reed Dickerson, deals with the freeze technique. The third chapter, by Robert J. Benes, is concerned with the techniques and difficulties of pricing by the formula method. The fourth chapter, the work of A. Moore Lifter, takes up the very complex problems presented by the necessity of pricing by specific authorization. The only definite case study involving a closely related group of commodities is presented in Chapter Five, in which David Kass goes into considerable detail as to the methods used and difficulties encountered in the pricing of solid fuels. The concluding chapter, by John W. Paschke, deals with the problem of pricing foods, and the techniques of distributor margin control.

It would, of course, be easy to criticise the organization of this volume, just as it has been easy to criticise the organization of others in the series, by pointing out that the editing leaves something to be desired. It is true that there is duplication of material, especially between the first two essays, for the second uses the subject of the first as a continuing example in its exposi-

tion of the freeze technique, thus frequently repeating what has already been said. This criticism is not so true of the material of the other chapters: in fact, for them, it can be said that instead of overlapping there is sometimes too little transition material. The development by which one method of control either grew from, or was compelled by another, is not sufficiently elucidated.

But although such criticism is easy—and correct—it would be hardly fair, in view of the avowed method and purpose of the series. From the first, with apparent full understanding of the inherent disadvantages of the method, it was planned to present the studies as a series of essays. We must, therefore, accept the plan of organization and go on to a consideration of this particular set of essays. It does not present a careful, closely reasoned study of the techniques of price control in all their aspects: it is rather an attempt to describe certain phases of the problem, and certain solutions which were used. The aforementioned careful, analytic study of the techniques of price control as practiced by the Office of Price Administration will not, I venture to say, be a book of 286 pages, as this one is; it will most likely consist of five volumes of a thousand pages each.

No one of these essays, on the other hand, is hammock reading for the dilettante. The approach is technical, and frequently a bit involved as to vocabulary. There are expositions which only the initiate can handle fluently, and sometimes he will find himself nonplussed. With all of this, too, I have no quarrel. The technique of price control was never designed for the amateur; it did not follow glittering generalities; it was difficult to originate, and far from simple to use. The Empire State Building did not rise upon generalized blue prints either. The difference is that the building of a material structure is known to be a highly technical job, and the technicians do it with little lay interference. Price control was conceived and had to be carried out in the scorching glare of Kleig lighted publicity, with much kibitzing from everyone, and no few anathemas. But the job still remained technical, and it had to be run by technicians. The amateurs frequently proposed price regulations, but they weren't price control regulations. (Read about the Yellow Draft Plan on page 238, *et seq.* of this volume.)

The essays do lack comprehensive and critical appraisal of the results of the methods dealt with, even though each one devotes a few paragraphs to that aim. This lack is the great defect of the volume. There is no definite statement about how each method failed to reach its goal—and each did fail to a greater or less degree, of that there is no doubt. No red signal flags have been set up to mark the pitfalls, so that future travellers may avoid them, and there is no over-all suggestion as to how to do a better job when next it has to be done. Perhaps we are too near in time to the facts to be able to do a good job of warning, but from the present look of things, someone would deserve well of his country were he at least to try it.

Only indirectly and with reserve is comment made about the political difficulties and congressional heckling which the men at high policy levels had constantly to undergo, all of which were a major distracting influence to the work of the agency. If Mr. Fairless had to spend as much time explaining to his Board

as, for instance, Mr. Bowles had to spend explaining to various congressional committees, there would be real reason for a steel shortage. Even now, the writers of the essays, mindful, doubtless, of past congressional browbeating are all too careful to keep from placing blame for some of the agency's failures where it belongs, namely on politics and on the Congress, the members of which always seemed to want price control, in general, but never specifically controlled prices when their pets were involved. It is my bitter feeling that a cold, implacable analysis of this official hamstringing of an essential war effort cries aloud for expression. This volume doesn't do it, although here and there a coy sentence is pregnant with meaning for those whose memory is good.

To give anything approaching a résumé of the material contained in the essays is, of course, impossible in a review of this length. A few selected facts and implications may be interesting. Before price control had run its course, more than 500 Maximum Price Regulations had been issued. Almost all of them had been amended at least once, and several of them had had hundreds of amendments. In addition, there were thousands of orders issued under the authority of some of the regulations, and tens of thousands of special adjustments. The necessary paper work was a burden and keeping abreast of the regulations a most difficult task for the field men, as well as for the business world.

Implicit in the essays is the fact that no one in America really knew, or knows, very much specifically about our economy and especially about the ways in which our "market" functions, and this ignorance is as rampant among members of an industry or trade as it is among the economists. (This book should be required reading for those teachers of economics who still lecture with debonair unconcern about the "American market," as if it were a single well-oiled, self-running machine. What a surprise they'd get!).

Since no one had the facts about the "historical" market, the agency tried to get them for itself. Frequently it called on the Bureau of Labor Statistics, which, with its trained staff, did yeoman service in making needed surveys. From such data the agency tried to arrive at some sort of rational bases for some of its controls, notably the food margin controls. Of course, statistical analyses were used, but it is noteworthy that after the curves had been carefully drawn, and divided into four types,¹ the final determination of the specific margin to be used in any particular case was still more by subjective judgment than by objective rule. In this particular field, Safeway Stores objected, citing the arbitrary method by which the agency arrived at its conclusions, but the Emergency Court of Appeals upheld the determinations, declaring in a most important decision that it was not the means of determination of price which were of primary importance, but rather, whether the price determined was "generally fair and equitable."²

Then, there were the difficulties of definition and of classification. For instance, should all stores be treated alike in the matter of food pricing,

¹ See the section titled "Analysis of Margin Data," page 229 and following.

² See page 286 for this important part of the decision.

whether or not they were large or small, single or chain?³ What is a margin? Is it figured on the cost of the article (that is the traditional method of our schools), or on the selling price (most "modern" businesses do it that way)? The agency finally came to call profit percentage based on cost a "mark-up," and one based on selling price a "margin." It was very easy to make a mistake, and a mistake could make a large difference in price. And what was an "in-line" price? Although the concept was rather widely used, no clear-cut definition was ever enunciated.

The General Maximum Price Regulation froze prices at the highest level charged in March of 1942. That's a simple statement, it would seem. But, to consider just one difficulty, what if a seller wanted to sell something in August which he hadn't sold at all in March of 1942? There had to be an answer to that one, and there was—not only one, but several. One is set forth at some length in the last paragraph on page 83. Not only this paragraph, but the one following it on page 84, are both most interesting in setting forth the difficulties inherent in saying precisely what is intended, in language understandable to the man who has to abide by the regulation. I am willing to make a modest wager that the figure derived (correctly) by the author for "average per cent mark-up," in his exposition of the simple example in the first paragraph at the top of page 84, would not be the figure derived by most of the people to whom the regulation applied. I could be wrong.

Even while I was a member of the staff of the Office of Price Administration, I used to be amazed, in my cloistral, midnight meditations, that the agency succeeded at all. A perusal of this set of essays does but increase that amazement. But the record speaks for itself: wartime price control was an over-all success.

Problems in Price Control: Pricing Standards. Edited by JAMES B. ECKERT. (Washington: Supt. Docs. 1947. Pp. xvii, 522. \$1.00.)

Problems in Price Control: Changing Production Patterns. Edited by BENJAMIN CAPLAN. (Washington: Supt. Docs. 1947. Pp. xiii, 441. 75c.)

These two studies in the historical series covering the activities of OPA describe the development of pricing standards by OPA and its predecessor, OPACS, between 1941 and 1946 and the problems met in seeking to maintain production of necessary items under conditions of wartime price control. Each of these volumes consists of a series of chapters written by different individuals on various aspects of the problem. These chapters are of uneven performance and extremely repetitious. Although they present a picture of the issues involved, there is no critical assessment of policies pursued by OPA during World War II. They should be useful, however, to students of public control and to historians of the war effort. They should likewise be of considerable value to those who are concerned with industrial mobilization

³ They were, in fact, divided into four classes. See page 243.

planning for another war. Finally, they should be of interest to economic theorists because of the incidental sidelights which they throw upon the structure and functioning of the American economy in times of both war and peace.

Pricing Standards is concerned with the standards used in establishing and adjusting price ceilings. These standards derived from several sources: congressional legislation, executive orders of the President, the directives of the Economic Stabilization Director and the Director of War Mobilization and Reconversion, and finally the Price Administrator and operating groups within OPA itself. The volume includes a chapter on the general nature and significance of OPA price standards and a chapter on each of the basic standards developed by OPA including the industry earning standard, the minimum product standard, the reconversion and transition pricing standards, and the decontrol standards. It also includes chapters on the basic legislative standards for agricultural commodities, the Bankhead-Brown Amendment applicable to cotton, and Barkley-Taft Amendment of 1946. Finally, there are chapters on the changing character of product price adjustments and on individual seller adjustments including adjustment of abnormally low prices under the General Maximum Price Regulation.

Pricing standards of OPA were closely associated with the techniques of control used in the early period of price control. At that time OPA depended to a large extent upon the techniques of freezing base-period prices or base-period pricing formulae. Consequently, the pricing standards established by OPA were concerned not with the adequacy of prices in general but rather with the conditions under which prices became unfair and inequitable and consequently required upward adjustment.

The basic standards developed by OPA were the industry earning standard and the minimum product standard. Under the industry earning standard, prices of an industry were considered fair and equitable so long as the earnings of the industry equalled or exceeded its earning in a representative peacetime period, with due allowance for changes in investment. In general, the representative peacetime period was taken as the years 1936-1939. The minimum product standard was developed for multiple-product industries to supplement the industry earning standard as a method for determining whether the level of ceilings on particular products was fair and equitable. As finally formulated, it provided that sales prices on particular products or product lines of a multiple-product industry should be sufficiently high to allow the producers of the bulk of the output by dollar volume to receive their out-of-pocket costs.

Both of these standards were essentially relief standards in their original conception. It is not surprising that OPA faced many difficult problems in defining the concept of an industry, in determining profits, in measuring changes in net investment, in selecting a representative base period, in defining "out-of-pocket" costs, and in determining a satisfactory measure of the "bulk of the output." Supplementary standards were developed for multiple-product industries with substantial single-line members, for segments

of industry in special economic situations, and for industries whose current earnings were abnormally distributed as between individual producers. More liberal standards were developed for industries subject to reconversion or transition at the end of the war.

It is interesting to note, however, the pervasive influence of the two basic standards which in rough form were adopted early in the war and their impact on the thinking and operations throughout the price control establishment. It is equally interesting to note how slow OPA was in developing explicit meaning for these general standards. It is clear that, given the general strategy of price control, these standards were extremely useful as interim devices designed to force industry to absorb cost increases and to minimize the immediate administrative burden of price control upon OPA. In retrospect, however, it may be questioned whether the adoption of these two standards was not taken too seriously by the price controllers and whether their preoccupation with holding the price line did not divert their energies from devising standards and procedures which might have been more effective both in facilitating the necessary adjustments within the economy and mobilizing public support behind the price control program. The Bankhead-Brown Amendment, Barkley-Taft Amendment, the prohibition of highest price-line limitations, and the controversy over reconversion pricing and decontrol standards are all examples of successful attack upon OPA's basic standards resulting from pressures of interested groups and the exasperation of congressional and public opinion. OPA's principal function was to facilitate the war effort directly through facilitating necessary production and indirectly through promoting social and political stability. Holding the price line was a tactic, not an end. It is probable, however, that if the principle of a controlled price system had not been in dispute, OPA might have moved more rapidly to a solution of the pressing problems of facilitating production.

Changing Production Patterns highlights the inadequacies of the pricing standards under the conditions which prevailed during World War II. This volume is concerned with several problems faced by OPA in maintaining the production of necessary commodities. Although price control seemed to work in the early period without developing serious problems of production, with the passage of time it appeared that the price incentives were such as to induce serious shortages in some critical areas such as food and low-price items of textiles and clothing. These relative shortages developed for various reasons. In certain cases they were the result of errors in original price ceilings, for example MPR 127 covering textile converters. In other cases they were the result of increasing incomes and the shift of demand from low-price to high-price items. In still other cases they were the result of differences in the profitability of various items of production in the base period and a desire on the part of the manufacturers to take advantage of the increasing demand for high-profit items under wartime conditions. Finally, in the case of the feed-food problems the difficulty arose from the fact that the relations between parity prices, which were the statutory guides to price

control in this case, were not the appropriate relations to encourage the desired pattern of food production. Consequently, OPA was faced with a series of crises in food, textiles, clothing, consumers' durables, and building materials.

It is to these problems that *Changing Production Patterns* is devoted. The study includes a section on the relations between OPA and WPB in developing price and production controls in textiles and apparels and a section on restrictive pricing designed to affect production patterns, such as the highest price-line limitations, MPR 127 controlling the converting industry, and the maximum average price plan (MAP). It also includes a section on various incentive pricing schemes developed for textiles, clothing, and consumers' durables and a section on the feed-food price problem.

With a few exceptions, the discussion is concerned primarily with general policy problems and makes only incidental references to the structure of the industries involved and the statistical effects of the policies pursued. However, these chapters throw a good deal of light on the pricing practices of various industries in both peace and war. It is clear from reading these chapters that although the economic system is not as sensitive as has been sometimes supposed, nevertheless there is considerable flexibility in the system. Over a period of time, resources are quite mobile under conditions of high-level demand. Even under wartime controls, manufacturers and distributors made substantial shifts in the direction in which they devoted their resources as a result of shifts in demand and differences in the profitability of various lines.

In the early period OPA clearly operated on the assumption that its principal objective was to hold the price line and that if serious problems of supply developed, the solution was to invoke production directives through WPB and the Department of Agriculture rather than to attempt to manipulate the controlled price structure so as to produce desired production patterns. The principal exception made to this was in the military goods area, an extremely important area which is hardly mentioned by either of the two volumes under review. Controversy soon developed between OPA and WPB, however, over the relative place of production directives and price incentives in insuring the desired production patterns. After considerable struggle between OPA and WPB, in which the Office of Economic Stabilization (OES) and the Office of War Mobilization and Reconversion (OWMR) were referees, it became clear that WPB's contribution to these problems would be small and consequently that need for price relief was greater than OPA had hoped.

This controversy served, of course, to delay the price relief and thereby helped to preserve the integrity of the statistical price line longer than might otherwise have been the case. The supply problems which resulted, however, led to scarcities which increased the cost of living more than the BLS index indicated. Moreover, the delay in facing these problems and the controversy over the methods to be used did much to weaken the support of the price control program by industry, Congress, and the public. It is unfortunate that those in responsible positions, especially in OES and

OWMR, did not resolve the controversy between OPA and WPB sooner.

These two volumes focus attention upon several major problems of price control in a wartime economy. To what extent should the objective of holding the price line become a dominant objective of the pricing agency? To what extent should price be used to facilitate the desired allocation of resources? To what extent should production controls be used in the civilian goods area? These are critical problems which must be faced by our war mobilization planners. These studies of the pricing standards used in World War II and of the problems of maintaining necessary supply deserve careful attention in all future planning.

JOHN PERRY MILLER

Yale University

Monopoly. By E. A. G. ROBINSON. (Cambridge: University Press. New York: Pitman Pub. Corp. 1941. Pp. xvi, 298. \$2.00.)

This book, one of the Cambridge Economic Handbook series, undertakes an analysis of the economics, forms, practices and effects of monopoly (and oligopoly), together with a survey of monopoly problems and public policy in the United States, Germany, and Great Britain. It is first-rate, as one would expect it to be.

The analytical portions of the book are tightly reasoned and tightly written; the author's skillful operation on monopoly pricing and output policies, and the relation of monopoly to productive efficiency and industrial stability is performed with confident precision. As a descriptive artist, Robinson is less conspicuously successful. He draws too heavily upon worn-out materials in the case both of the United States and Great Britain; the discussion of monopoly in Great Britain is a little remote from the firing line; and the handling of American antitrust legislation and litigation is inadequate.

Robinson's conclusions are neither new nor startling, but they gain strength from development and formulation at his hands. He belongs to the school which finds (correctly, in my judgment) the "monopoly problem" fully present in oligopoly, and which sees antitrust actions as resetting rather than solving our difficulties:

Two very important conclusions follow. . . . First, monopoly price is fully as much a consequence of the attitude of a small number of firms to each other, of the assumptions they make regarding each other, as of formal or informal agreements. We cannot assume that where there is no agreement, even of a tacit nature, competition exists. It all depends upon what one manufacturer thinks another manufacturer is going to do. It follows, therefore, that what we may call the detective story approach to the study of monopoly, the search for mysterious hidden agreements, is really a waste of time. Their existence may prove something, their non-existence proves nothing. Second, if we discover a condition of monopoly it is highly unlikely that we can with any certainty re-establish a condition of competition merely by breaking up that monopoly into a few constituent parts. It is very much more likely that

we shall substitute the uncertainties of a cat-and-mouse monopoly for the certainties of an open one (pp. 29-30).

In view of arguments recently advanced, it is gratifying to come upon Robinson's conclusion that while a monopoly may be able to stabilize the fluctuations in its own income during a depression, "it is likely to achieve its ends only at the cost of increasing the fluctuations both of its own output and of the incomes and welfare of others." This constitutes

a most serious indictment of monopoly. For we must not forget that it is the main justification of the existence of the entrepreneur that he carries the main risks of industrial production. If, through the creation of monopoly, he seeks to transfer those risks to the shoulders of others, he will inevitably suffer the universal fate of all redundant members and be replaced by some new organism better fitted to fulfill this function. Thus those who seek through monopoly to make the world safe for capitalism are probably doing more than anyone to ensure its ultimate destruction (p. 167).

The one point at which Robinson's analysis seems to me to be less than penetrating is in his treatment of the problem of economic power (p. 183 ff.), although it is certainly to his credit that he sees monopoly as a problem of power as well as of profit. Irresponsible power, more than any other characteristic, seems to me to constitute the undesirable feature of monopoly; but I would emphasize that it is the existence of such power and not alone its misuse that is abhorrent. Certainly its possible employment along the lines suggested by the author (pp. 185-86), where the monopolist chooses to be guided by economic considerations, does not impress me as a striking example of the evil of monopoly. Beyond this, however, and in the same area, Robinson in common with a number of other writers appears to confuse the problem of concentration of power within the corporation (consequent upon the growth of large-scale corporate enterprise) with the problem of concentration within the economy (consequent upon the growth of monopoly). The two problems are interrelated, of course, and concentration of control within the corporation certainly aggravates the dangers flowing from monopoly; but the problems are quite distinct and should be so treated.

The author has no pat remedy for monopoly. He recognizes that "when we turn from the present to the future, and from what is to what ought to be, we move inevitably from the field of objective fact into the field of subjective judgments. We cannot prove by logic how we ought to act" (p. 273). He considers three alternative policies—inaction, mitigation and abolition—and points out that the choice between them cannot be made on economic grounds alone. The decisions involve

our most deep-rooted political, social, economic, even religious principles. But we cannot be blind to these broader issues which impinge upon our studies, and pretend that they lie beyond the horizon of a strictly defined economics. If we seek to exclude them wholly from our scope, and more especially from the scope of an examination of monopoly, we shall confine ourselves to a profitless academic discussion of an unreal world (p. 288).

This is sound. But he might well have gone on to emphasize that we would be wise to make up our minds. With the forces of concentration growing stronger by the hour, a failure to decide constitutes in itself a continuing decision in favor of monopoly.

BEN W. LEWIS

Oberlin College

The History of Basic Metals Price Control in World War II. By ROBERT F. CAMPBELL. Studies In History, Economics and Public Law, No. 541. (New York: Columbia University Press. 1948. Pp. 263. \$3.25.)

This is a case study of wartime government control in an area in which price increases were kept to a minimum. The author states that the work, submitted as a doctoral dissertation, was conceived and executed while he was on the staff of the Office of Price Administration with the benefit of free access to official files.

Basic metals included in the study are iron, steel, aluminum, copper, lead, zinc and the scrap metals. A composite index of basic metals prices, on a monthly basis, 1939-1945, is compared with the Bureau of Labor Statistics wholesale price index by way of pointing up "success" in stabilizing metals prices. Monthly price movements for each of the metals included in the composite index are presented in an appendix.

Emphasis is placed upon administrative aspects of government price control as related to this particular group of commodities. Five of the eleven chapters cover such topics as techniques of price control, pricing standards, adjustments of price, etc. In addition, two chapters are wholly devoted to the premium price plan for copper, lead and zinc.

In the chapters on the administration of price control the author undertakes to present the major developments and considerations that were pertinent in policy decisions. For this purpose he has drawn upon his own experience and upon interviews with various members of the OPA staff in addition to using official statements and office memoranda. In discussing the early, informal, controls the author indicates the significance for the program of prewar pricing practices and the role of "administered" prices. The author points to the later difficulties resulting from functional division of authority and in a concluding chapter he points to the need for closer integration of production management, price control and labor allocation in the event a comparable program were put into effect at some future date.

Discussion of the premium price plan for copper, lead and zinc and a concluding chapter entitled "Prices, Production, Costs and Profits under Price Control" contain material and data of particular interest to the economist. The circumstances which cause a condition of "increasing costs" in mining operations are discussed without a labored use of the technical term or the marginal concept. Similarly, the non-ferrous metals differential, or discriminatory, pricing program is viewed in terms of economical government procurement and contrasted with the bulk-line pricing system followed in World War I.

At various points Dr. Campbell acknowledges the value of several of the early volumes in the OPA and WPB series of historical studies and in his Preface he calls attention to the OPA sponsored study, *Studies in Industrial Price Control* which appeared after his own work was completed. Several further volumes in the series have appeared since then, and the study *Problems of Price Control: Stabilization Subsidies* presents collateral material especially useful in considering savings effected by the government through use of the premium price plan.

As distinct from the government sponsored studies, the contribution of *Basic Metals Price Control In World War II* lies in the discussion of specific problems associated with government control over a group of related, standardized commodities, oriented in terms of the over-all interagency program. As such, it is a useful addition to historical studies on price control and on basic metals.

Public Utilities; Transportation; Communications

Men, Cities and Transportation: A Study in New England History, 1820-1900. By EDWARD CHASE KIRKLAND. 2 vols. (Cambridge: Harvard Univ. Press. 1948. Pp. xvi, 528; ix, 499. \$12.50.)

The literature of transportation history is enormous, yet its quality leaves much to be desired. Many corporate histories of our major railroads carry the story of construction, finance and consolidation, but seldom contribute much to an understanding of the historical and economic role filled by the lines. Popular histories retail the romance of the rails and of other types of transportation—the early turnpikes, the canals, and more recently, in great profusion, the airways. All of these works lack comprehensiveness. Few pretend to weave the story of transportation into other phases of contemporary history in order to trace the reaction of improved transportation upon the economy and the reciprocal impact of the economy upon the course of transportation development. Few attempt to integrate the technical developments of the means of transportation with their reflection in service and rates and thus in the fortunes of industries, communities and regions—in short, to place transportation into focus among other factors responsible for economic growth and decline.

Aside from a few popular works, transportation history has for the most part been treated fragmentarily since the excellent *History of Travel in America* by Seymour Dunbar (4 vols., 1915) and the comprehensive *History of Transportation in the United States Before 1860* by Caroline E. MacGill and associates (1917). There is no recent history of transportation in America and there are few regional studies. New England, an area set apart somewhat by geographical and historical determinants, has a certain distinctiveness of transportation development which has given rise more often than other regions to treatment as a whole. The excellent *Formation of the New*

England Railroad Systems by George P. Baker (1937) and the more recent and popular *Steelways of New England* by Alvin F. Harlow (1946) are examples, but their objectives were limited and their treatment is specialized. Now comes, however, a serious historical study of New England transportation which in scope and scholarship surpasses earlier efforts.

Professor Kirkland suggests his point of view in the preface: "It is time for us to subordinate the phases of promotion and construction and explore, more fully than we have hitherto, the problems of rates, services, securities, technological changes, government policy, labor and management. . . . I have simply sought to treat the New England transportation system as a human response to the changing needs and ambitions of that area" (p. vii). A careful reading of these highly interesting pages will demonstrate that he has achieved substantial success in what is no doubt the most significant regional transportation history produced in recent decades. To the economist, historian or geographer the work is of large value in understanding an important element in the development of the New England economy.

The view of New England's pre-railroad transportation presented here is the most complete this reviewer has encountered. Of particular interest is the author's careful exploration of the routes taken by the western trade and of the relationships established between the ports and the interior as a result of topographic conditions unsurmounted by economical transport. The roots of Boston's difficulty in securing a share of the western business are well developed. The whole picture is thoroughly documented by reference to contemporary sources, many hitherto unexplored for their potential contribution to the history of transportation.

The era of railroad promotion is enriched in this treatment by the author's continuing concern with the specific hopes and aspirations of localities and groups, with the struggles surrounding state and local aid, and with the problems in experimentation encountered by not merely the railroad builders and operators but by public bodies as well. Of particular interest is the discussion of the early conflict of ideas with respect to proper rate-making policy centering about the divergence in the viewpoints of the Boston and Worcester and the Western Railroad managements. The sweeping penetration of boards of directors into such managerial concerns in this early period is well brought out. The driving urge for end-to-end consolidation even where the independence of connections was without threat developed naturally from the problems of making joint rates and agreeing upon divisions. It collided at once with the deep-seated antipathy of the community to monopoly translated into terms of mere size of the corporate enterprise.

Boston's frustration in its efforts to channelize a significant portion of the western trade through its own commercial and port facilities provides an important connecting thread through much of the first volume. The nature of the physical barriers which turned trade into the less costly channels toward New York during the pre-railroad era is carefully detailed, the characteristics of the resulting trade indicated, and the preferred transportation routes described. To many it will come as a surprise that the Lake

Champlain-Hudson River-Long Island Sound route was a customary one for freight movement between western New England and Boston and other port cities. And such traffic passed through New York and was in imminent peril of being short-circuited. The affinity of the Connecticut Valley towns for New York as their trade center is well known.

These, then, were the conditions which Boston aspired to alter by means of railroad development. Her success was decidedly limited, for New York State stood athwart the routes to the greater west, the New England railroads got no farther than Lake Ontario and Troy, and their connections from thence westward were in unfriendly hands. As the story of the physical development of the railroad system is chronicled, so also are the vicissitudes of the rate structure portrayed with care. Although this is a regional history, it contains a more thorough exploration of the efforts to control the trunk-line rate wars and to bring order into the rate structure east of Chicago than do other works which treat of this subject. It shows clearly, too, the conflict between the desires of the New England farmers for high rates on the western produce and the desires of the commercial centers for low rates on the same traffic.

Much emphasis is rightly placed upon the moving spirits behind the growth of improved transport—the prophets, promoters, financiers, engineers, critics and others connected in one way or another with the railway enterprise. The closeness of the ties between railroad promotion and politics are perhaps more concretely portrayed here than in most other works of railroad history. And the few dissenting representatives of the public interest are always appearing in these pages with their crusades for reform. New England, of course, gave rise to the earliest railroad commissions and a few of them were clothed with powers going beyond those merely of investigation and report. The Massachusetts Commission, reflecting the strong personality and strenuous endeavors of its first chairman, Charles Francis Adams, Jr., led the way in much that was important in the improvement of safety and the regularizing of rates and accounts. This work suggests that the accomplishments of these early state commissions have been hitherto underrated and that they deserve greater emphasis in the history of transportation regulation. Of great interest is the conservatism of New England railroad managers. The practical tradition here went to extremes which set back the application of proved technology by many years, long after successful use had been made on the roads of other regions. Indeed the long adherence to tried practice and rule of thumb is perhaps without equal elsewhere and at other times in American railroading. It would appear that the Massachusetts Commission particularly deserves much credit for jolting the railway managers out of their comfortable life in the past.

In sum, here is a contribution not merely to the synthesis of the hitherto known history of the New England transportation system, but one which also adds in significant ways to our knowledge of that history. Moreover, it is a well-written and consistently interesting account.

Land Economics; Agricultural Economics; Economic Geography

Real Estate Analysis. By WILLIAM H. HUSBAND and FRANK RAY ANDERSON.
(Chicago: Richard D. Irwin. 1948. Pp. vi, 576. \$5.00.)

Whatever connotation the term "real estate analysis" may have for the reader, it likely will not fit the content of this book. But it is of little importance that the volume is mistitled for between its covers is a most useful compendium of real estate knowledge; the field is well covered and the text reads the more easily by reason of a mildly discursive style and a thread of politico-economic philosophy. The authors see as the paramount real estate problem the "reconciliation of the public and private interest."

This volume might be characterized as a work of descriptive or behavioristic economics. It is institutional economics without a theoretical binder. There is no distinguishable "economics" of real estate, no orderly theoretical framework which ties together the subject matter into a recognizable structure; only by implication is there a linkage with general economic theory. But in spite of a preoccupation with social control and governmental intervention, there is a real understanding of the economics of the real estate market though it be expressed in other than economic jargon.

The first of five parts of the volume considers Real Estate and the Economy with chapters on the institutional aspects of real property, the importance of real estate in the national economy, a too brief discussion of urbanization, the urban land use structure and city finances, and final chapters on land development and the construction industry with a good presentation of the major problems of house building. Part II is a useful pocket text on the fundamentals of real estate law. Part III, The Real Estate Market, contains excellent chapters on the factors and processes of the urban land market and its cyclical aspects. There is a good chapter on real estate value and less useful discussions of the appraisal process, selling real estate, and property management.

The strongest section of the book is Part IV, The Financing of Real Estate. This strength reflects the background of the senior author, William H. Husband, a former professor of finance, and successively member of the Home Loan Bank Board, manager of a savings and loan association, and presently, general manager of the Federal Savings and Loan Insurance Corporation. On a subject which so rarely receives adequate treatment in current business and economic writings, it is refreshing to read a discussion of substance. The chapters cover the nature of mortgage risk, the operations of the mortgage market, sources of funds in primary and secondary markets, the processes of mortgage lending, and sound lending practice. There is an understandable emphasis on federal intervention in the home mortgage field. From authors so well qualified to pass judgment, the reader might wish for incisive evaluation of governmental policy, but a discreet reticence on the part of authors serving in governmental posts is not unexpected.

The final group of chapters, Part V, The Public Interest, provides the authors with the opportunity to express a middle-of-the-road philosophy on

the public housing issue. There are warnings to private industry to solve its own problems before housing shall be fully socialized and warnings to the public housers that too much governmental intervention endangers our basic economic system. The chapter on taxation states the case for the relief of real estate from an unjustified burden; the discussion of eminent domain is soundly legalistic; planning and zoning are briefly considered with a good section on urban redevelopment. The discussion of the veterans' housing program is primarily descriptive and the final chapter chews over the public-private conflict in the real estate field without finally digesting it.

Except for the section on real estate finance, this volume does not add a great deal to the real estate books of recent years. The several topics have been covered more or less adequately by others, for example, by Colean,¹ Hoagland² and Weimer and Hoyt.³ The authors show less than adequate interest and understanding in dealing with the land use structure of cities. They are not too successful in presenting an "economics" of urban land for they have segmentalized and institutionalized the subject matter until the underlying economic relationships, which might have been laid bare for all to see, are somewhat obscured. But the book does provide an up-to-date descriptive analysis of the primary factors and processes which constitute the real estate market and the institutional framework within which they operate.

Labor

Labor Unions in Action. By JACK BARBASH. (New York: Harper. 1948. Pp. x, 270. \$3.50.)

The outpouring of articles, pamphlets, monographs and textbooks covering various phases of industrial relations has been impressive and almost frightening during the past year or two. Of all these publications, *Labor Unions in Action* is one of the most sensible and least pretentious. Mr. Barbash is widely acquainted with union leaders, familiar with the literature of industrial relations, and capable of discussing controversial subjects without undue excitement. (Only on the subject of "Communist Unionism" does he become really emotional.) As a result, he has written a reasonable and informative volume describing how trade unions are organized, administered and led.

The scope of *Labor Unions in Action* is indicated by the chapter titles: Union Structure and Jurisdiction, Union Government and Administration, Collective Bargaining, The Strike, Extracurricular Union Activities, Union Leadership, and so on. At first sight the approach appears to be quite customary, since all of these subjects are described in previous works such

¹ Miles L. Colean, *American Housing* (New York, The Twentieth Century Fund, 1944).

² Henry E. Hoagland, *Real Estate Principles* (New York, McGraw-Hill, 1940).

³ Arthur M. Weimer and Homer Hoyt, *Principles of Urban Real Estate*, Rev. ed. (New York, Ronald Press, 1948).

as those of Millis and Montgomery, Peterson, and Taft. Mr. Barbash's treatment is distinctive in several respects, however. First is the cool and dispassionate analysis of jurisdictional disputes, working rules, general strikes, picket-line violence and other conventional objects of indignation. Second is the emphasis on opportunism as the guiding principle of union structure, jurisdiction, and strategy. Third, and most interesting, is the vantage point of the analysis. Mr. Barbash is looking through the eyes of the labor organizer, the business agent, the local union president, the international representative, and the other non-commissioned and commissioned officers of the labor movement. As he states, "the perspective throughout is that of the union spokesman who is candidly describing and interpreting his own behavior." For all our studies of pricing and production, most of us know next to nothing of how the business executive really operates; and despite the current effusion of literature on industrial relations, the world in which the union leader moves is still for the most part dark and unexplored.

The picture which emerges is one of an essentially opportunistic institution endeavoring to make its way in the world and keep its head above water. There are great diversities in structure, program and ideology; but "for most unions, organizing new members, administering the affairs of the union, collective bargaining and strikes are the core functions because the maintenance of the union as a going institution depends on the adequate discharge of these functions." The run-of-the-mill union leader is revealed to be neither a latter-day saint nor a cynical and corrupted autocrat; he is governed primarily by the immediate pressures converging upon him, secondarily by his notions concerning "good trade unionism," and to a much smaller extent by his ideological sentiments.

Mr. Barbash's naturalistic approach has great advantages, but it also has a price. The basic limitation is the limited insight of the union leader, who is not especially concerned with the ultimate significance of his activities nor in a good position to appraise it. Thus, it is true that "the usurpation of management prerogatives in any wholesale sense has little attraction for the union as an end in itself"; but this does not mean that, over the years, unions will not insist on playing a continuously larger part in the administration of industry. To state that "management prerogatives are of concern only . . . as they appear to impinge on wages, hours and working conditions" is an accurate description of trade-union mentality, but of no great significance for the long run. Similarly, "it is extremely unlikely that the organized labor movement as a movement, or any substantial segment of it, will lend itself seriously to any revolutionary political upheaval in the United States"; but this does not settle the chronic questions of tendency which the Webbs, Perlman, Tannenbaum, and other students have wrestled with. What is the political drift of the labor movement as it moves along in its opportunistic way? Is it undermining the structure of capitalism, or buttressing it? Who is on the wave of the future—Beck, Lewis, Dubinsky, Reuther or Bridges?

Mr. Barbash does not throw much light on questions of this kind, but then he does not claim to. His book will stand on its own merits as a valuable

account of what makes unions tick and why union leaders behave like union leaders.

ARTHUR M. ROSS

University of California, Berkeley

Personnel Administration: A Point of View and A Method. By PAUL FIGORS and CHARLES A. MYERS. (New York: McGraw-Hill. 1947. Pp. ix, 553. \$4.50.)

This book on personnel administration is designed as a college textbook. It primarily presents and provides an illustrative application of a technique of analysis of personnel problems. It avoids all industrial relations and economic problems as outside of the personnel man's primary interest. The authors build upon the work done by the Harvard Business School at the Hawthorne plant of the Western Electric Company and share the interpretations of human relations popularized by F. J. Roethlisberger. The cornerstone of this book is therefore the study of a worker's attitude to his job, management, and supervision. Industrial case work is the approach toward the solution of problems. The interview is the tool for getting the facts. Employee counseling, only casually referred to, is the technique for handling the more difficult cases which the regular management line organization is not prepared to solve.

In this context, the successful personnel administrator aims at creating industrial team work to assure "maximum efficiency and competitive advantage" in a plant directed and controlled by top management in its own economic interest. This goal can be best achieved by relieving employee dissatisfactions, *i.e.*, "anything that disturbs an employee whether or not he expresses himself in words."

At the outset the authors report themselves as being handicapped by the current lack of knowledge, as they inform the reader in a footnote (p. 40), that "there is at present no clear-cut agreement as to what these principles (of personnel administration) should be." The book therefore has not a set of unifying principles for interpreting human behavior, though the principal subject is human attitudes. There is no statement of social and economic goals for personnel administration to achieve other than those prevailing among the top management of the industrial enterprise.

The authors do not evaluate the different types of dissatisfactions and the priorities which should be observed in relieving them. Can one hope to resolve all? Are our present industrial, technical, economic, and institutional arrangements compatible with the goal of eliminating human dissatisfaction? Is dissatisfaction an adequate index of the excessive costs of work or economic and social activity? Can all causes of dissatisfaction be reached through the personnel management of the individual industrial enterprise? What do you do about the residue of unrelieved dissatisfaction? What is the personnel man's responsibility in dealing with unresolved personal conflict? How adequate for the purpose of eliminating industrial dissatisfaction is the approach by way of the individual dissatisfaction? These and many kindred problems

are not raised in this book. The discovery of personal maladjustment because of personal conflicts has narrowed the range of interest in the "labor problem."

By building their system of personnel administration around a method of analysis, the authors subordinate the discussion of substantive matters to the description of the procedure of handling them according to this approach. The book acquaints the personnel administrator with the case-method approach toward relieving worker dissatisfaction with the hope of advancing management's objectives. The interviewing technique is used to get data on attitudes. The information is to be analysed according to the "situational thinking" process which requires the personnel administrator to consider the technical features, the human factors, the principles (which are unavailable) and policies, and the time factor.

With these aids the personnel administrator can perform the following staff functions: (1) "advise and assist the line organization in the personnel approach (skillful handling of people both as individuals and as group members); (2) to diagnose the stability or morale of the organization as an effective work team, by means of various indexes of team work such as productive efficiency, absenteeism, accidents, labor turnover and internal mobility, and complaints and grievances; and to keep the line management informed of actual or potential difficulties that need their joint attention; (3) to provide personnel procedures and services such as recruitment, hiring, selection, training, wage and salary administration, safety education, etc., as an aid to the line officers in getting more effective results through the people under them; (4) to secure coordination and control of these activities through top management, which has full responsibility for seeing that they are uniformly and consistently administered."

The text is most explicit and confident in discussing the methods of diagnosing organizational stability and in dealing with "the building and maintaining work teams" as they relate to personal relations and reactions. In the analysis of substantive problems such as wages and hours and the presentation of the issue of employee participation in production problems the authors limit their discussion, take highly cautious and qualified positions, and do not fully relate the handling of these crucial issues to their main theme, namely, handling human dissatisfaction.

The overwhelming interest in method of analyzing problems makes the book most useful as a practical interpretation of the findings of the Hawthorne inquiry. A student of personnel problems would have to use other texts to gain actual instruction and practice in interviewing, in the analysis and understanding of human behavior and motivation, in the administration of specific personnel techniques, in industrial relations, labor problems, social movements, trade-unionism, and current economic and political problems. The text presents little information on the limitations of current personnel techniques, their misuse, and the unrest created by their application. Supplementary data would have to be distributed to acquaint the student with these matters. The reader is not encouraged to develop a scientific attitude

toward these techniques as the authors fully adopt the current management "code of the ways of organizing and treating individuals at work."

Trade unions are approved by the authors but they assign them a modest role within this system of management controlled personnel administration. It is to aid in "opening a new channel for complaints." The authors do not inquire into the share of responsibility the union should have in resolving dissatisfaction and its effect on the duties and rights of management.

The trade union arises from the long period of repression and second-rate citizenship suffered by workers. It expresses his frustrations and hopes, and yearnings. They arise from the experiences both within and outside the plant. One gains the impression that the aim of this proposed approach is to minimize the dissatisfactions associated with the job, management, and supervision. Possibly, it is hoped thereby to divert workers' dissatisfactions. Will the volume of dissatisfaction be reduced? What new target should the dissatisfaction seek? What success can such an approach have? Will it lead to even greater frustration?

Management sorely needs data and analysis which will give it a better understanding of the "labor problem." Adequate personnel administration can be built only on a broad understanding of the worker, his language, his personality (which is vastly different from the prototypes commonly proposed to management), his institutions, his values and demands. The social scientist has unfortunately done little to enlighten our American people on this score. An adequate textbook must rest on a broader base of knowledge and inquiry than is offered by this book.

This volume is supplemented by a rich collection of well-presented case histories. Questions are submitted to aid and guide discussions and to illustrate the method of analysis. The rounded bibliography definitely complements the text and offers the student guides on the source of ideas and further development of specialized knowledge.

SOLOMON BARKIN

New York, N.Y.

Population; Social Welfare and Living Standards

Population Analysis. By T. LYNN SMITH. (New York: McGraw-Hill. 1948. Pp. xii, 421. \$4.50.)

This book, which is primarily a study in demography, has been written as a text for an introductory course in population. The purpose of the author is to summarize important population facts and to stress proper methodology in population analysis. In his opinion, the emphasis by others on what is generally termed "population problems" is to be avoided. "The avoidance of the pathological emphasis [on such problems] is deliberate." He desires to train the student in the techniques of population analysis and does not believe that it is desirable to deal with many phases of population study which he regards as entirely speculative and philosophical.

The material for this study is divided into six main divisions or parts.

These parts are as follows: number and distribution of the population; composition; the vital processes; migration; growth; and conclusion. The general plan is to begin with an analysis of world data and conclude with a study of the figures for the United States. Part I consists of a single introductory chapter which gives estimated population throughout the world by countries and concludes with the number and distribution of people in the United States. These figures together with land areas emphasize the unequal distribution of people throughout the world. There is also included a short discussion of the concept of the optimum population. In Part II will be found a detailed analysis of population by race, age, marital and educational status, religion and occupation. The subjects of fertility and mortality, called the vital processes, are taken up in Part III. Here the student will find an interesting treatment of birth and death rate differentials, the problem of measurement of fertility, and the declining birth rate. The study of migration in Part IV comprises four chapters. An attempt is made in this division to summarize the important sociological studies dealing with the selectivity of migration. One chapter is devoted to internal migration. The growth of population, together with the related topics dealing with techniques for estimating this growth, are treated in one single chapter. Smith believes that an official estimate for our next census of approximately 145,460,000 is about one and one-half million too low. He has little regard for any idea that some practical use might some day be made of the concept of the optimum population. In the final part there are no elaborate or striking conclusions.

In keeping with the objectives set forth in the beginning, there is a plea for a more thorough analysis and study of demographic materials rather than speculative and unfruitful discussions. Studies of actual demographic materials are much to be preferred over the theories of "armchair philosophers." Only by the assembly, classification and study of population facts can we make the analysis realistic and meet the need for many public services such as education and health. No attempt is made to outline any definite population policy for the United States. Our immigration policy, he says, will come in for increasing attention. It is the author's opinion that no national policy with respect to the fundamental matter of the birth rate is likely to be developed in the near future as the question of birth control is a highly controversial issue.

When the reader examines this book and compares it with *Population Problems* by such writers as Thompson or Landis, he will find that the author has succeeded well in leaving out much material considered to be irrelevant and unnecessary. Here he will not find the familiar discussions of such topics as "danger spots," the city, or the various population theories. It is difficult to get away from habitual ways of thinking. The study of population is often said to begin with Malthus, yet there is only slight mention of him, in the last pages of the book. The name of Malthus is not listed in the index. The author is unalterably opposed to the whole idea of "mankind at the crossroads," yet nothing is said to refute the belief which

many still hold that there is an essential element of truth in the Malthusian doctrine in the long run. Little is given about the population policies of foreign countries or of the policies which have been discussed and proposed for this country. Smith has elaborated numerous techniques of population analysis and has left out some of the most basic questions and problems in the entire field.

Much reliance is placed upon the graphic methods used in this study, many of which are said to be original with the author. The most frequent type of chart is that of a map with density or other quantitative data represented by circles (Fig. 86, p. 179). This map chart with balls for quantitative data is repeated many times throughout the entire book (pp. 22, 41, 52, and numerous others). The difficulty of making accurate comparisons from maps of this character is a very old and familiar fact. Larger quantities are better shown by a large quantity of symbols, not by larger symbols. "We must remember that if one circle has a diameter twice as great as another, then the first circle has an area four times that of the second."¹ To overcome this objection, the author often sets out in the legend various circles with figures. It is not at all certain that the general criticism of this type of map chart has been overcome. It seems certain that many readers will have difficulty in following the data of various charts with curves showing figures of mortality or birth trends. The differences between the curves are so slight and there are so many curves on the chart that it is almost impossible in some instances to follow those of a particular country (for example, see pp. 136 and 224).

Although this book will probably not displace the type of population text now in general use, it will provide valuable supplementary reading material. It contains an abundant amount of demographical material brought up to date. The general conclusions based on this material are sound and free from bias. Several valuable suggestions for improving statistical data are given, and there are many interesting facts about the historical development of methods and practices. Population students will welcome Smith's book as another valuable study in a field of learning in which there is a constantly growing interest.

This volume consists of papers originally published in two 1947 issues of the *Revue d'Economie Politique* as follows: *La population*, by H. Bunle; *L'évolution des prix depuis la guerre*, by R. Rivet; *Le revenu national français*, by R. Froment et P. Gavanier; *Dommages, réparations, reconstruction*, by J. Vergeot; *La législation fiscale*, by L. Trotobas; *Le marché de l'argent a court terme*; *Le marché des changes*, by P. Vigreux; *Les banques*, by A. Pose; *La bourse des valeurs*, by J. Dessirier; *Les émissions*, by P. Haour; *Les caisses d'épargne*, by H. Anglade; *Les assurances*, by J. Fourastié; *La production agricole*, by P. Fromont; *La production industrielle*, by S. Béracha; *L'organisation professionnelle*, by G. Liet-Veaux; *Les échanges intérieurs*, by A. Piatier; *Le commerce extérieur*, by J. Weiller; *La balance des paiements*, by R. Jolivot; *La législation commerciale interne*, by A. Tunc; *La politique commerciale et les accords commerciaux*, by J. Naudin; *L'évolution des transports*, by J. Mothes; *La marine marchande et les ports*, by J. Marchegay; *L'Union française depuis la guerre*, by J. Pellier; *L'évolution des salaires depuis 1938*, by J. Lehoulier; *Le mouvement ouvrier et la politique syndicale*, by G. Dehove; *La législation sociale*, by H. Bartoli; *Assurance sociale et sécurité sociale*, by E. Antonelli; *Le ravitaillement en France depuis 1940*, by A. Heilbronner; *Habitations et logement*, by M. Aucuy.

Gesamtschau der österreichischen wirtschaf im jahre 1947. (Vienna: Österreichisches Institut für Wirtschaftsforschung. 5. Sonderheft, 1948. Pp. 52.)

Trends in American capitalism; profits and living standards. (New York: Internat. Pubs. 1948. Pp. 128. \$1.50.)

Statistics and Econometrics

CROXTON, F. E., and COWDEN, D. J. *Practical business statistics*. 2nd ed. (New York: Prentice-Hall. 1948. Pp. xviii, 550.)

SAYRE, R. A. *Consumers' prices 1914-1948*. (New York: Nat. Indus. Conference Board. 1948. Pp. 86.)

A substantial portion of the study describes the methods and procedures used in constructing the index.

WILKS, S. S. *Elementary statistical analysis*. (Princeton: Princeton Univ. Press. 1948. Pp. xi, 284. \$2.50.)

Report of the Social Science Research Council Committee on analysis of pre-election polls and forecasts. (New York: Soc. Sci. Research Council. 1948. Pp. 18, mimeo.)

Selected world economic indices. (Lake Success: U.N. Dept. of Economic Affairs. 1948. Pp. 53.)

Economic Systems; Planning and Reform; Cooperation

HEATON, H., and JOHNSON, A. *Socialism in western Europe*. Headline ser. no. 71. (New York: Foreign Policy Assoc. 1948. Pp. 62. 35¢.)

VOZNESENSKI, N. A. *The economy of the U.S.S.R. during World War II*. Issued in co-operation with the Am. Council of Learned Societies. (Washington: Public Affairs Press. 1948. Pp. 103.)

The original Russian was reviewed in the September, 1948 issue of this *Review*.

Cooperatives in postwar Europe. (Washington: Supt. Docs. 1948. Pp. 22. 15¢.)

Ier congrès international de l'Économie Coopérative, 15-20 novembre 1947, Paris—rapports principaux et quelques extraits des interventions. (Paris: l'Économie Coopérative. 1948. Pp. 54, mimeo.)

Review of the co-operative movement in India 1939-46. (Bombay: Reserve Bank of India. 1948. Pp. 111.)

National Income and Social Accounting

EAKIN, F. *Price problems—an accounting report*. (Decatur, Ill.: Econ. Accounting, Inc. 1948. Pp. 43. \$1.)

Income receipts of individuals in Maryland: flow of consumer purchasing power; department store sales as income forecaster. Stud. in Bus. and Econ., vol. II, Dec., 1948. (College Park: Univ. of Maryland Bur. of Bus. and Econ. Research. 1948. Pp. 12.)

International bibliography on income and wealth, Jan.-Sept., 1948. Annotated quarterly report prepared in cooperation with the Statistical Office of the United Nations. (New York: Nat. Bur. Econ. Research. 1948.)

Business Fluctuations; Prices

ARDANT, H. *Les crises économiques*. (Paris: Flammarion. 1948. Pp. 437.)

BABSON, R. W. *If further inflation comes*. Rev. ed. (Philadelphia: Lippincott. 1948. Pp. 240. \$1.50.)

HOPKINS, E. *The high crime of inflation: how to restore the purchasing power of the dollar*. (New York: Author, 255 West 43rd St. 1948. Pp. 217. \$4.)

WYTTEBACH, E. *Die wechselseitige konjunkturabhängigkeit von landwirtschaft und industrie in den USA, 1919-1941*. (Bern: A. Francke. 1948. Pp. 250. 28 sw. fr.)

The business outlook 1949. A forum discussion. Stud. in bus. econ. no. 19. (New York: Nat. Indus. Conf. Board. 1948. Pp. 56. 50¢.)

Council of Economic Advisers third annual report to the President, December, 1948. (Washington: Supt. Docs. 1948. Pp. 38. 15¢.)

The economic report of the President to the Congress, January 7, 1949. With a report, *The annual economic review, January 1949*, by the Council of Economic Advisers. (Washington: Supt. Docs. 1949. Pp. v, 140. 45¢.)

Monetary and fiscal policy for greater economic stability. A statement on national policy by the CED Research and Policy Committee. (New York: Committee for Econ. Development. 1948. Pp. 55, mimeo.)

Wholesale prices, 1946. (Washington: Supt. Docs. 1948. Pp. 137. 25¢.)

Money and Banking; Short-Term Credit; Consumer Finance

AFTALION, A. *Monnaie et économie dirigée—la valeur de la monnaie dans l'économie contemporaine*. (Paris: Recueil Sirey. 1948. Pp. 414.)

BRADFORD, F. A. *Money and banking*. 6th ed. (New York: Longmans, Green. 1949. Pp. xvii, 860. \$4.75.)

DIETERLEN, P., in collaboration with RIST, C. *The monetary problem of France*. (New York: King's Crown Press, for the Carnegie Endowment for International Peace. 1948. Pp. xvii, 98. \$2.50.)

- HALAAS, E. T. *Impact of the war on commercial banking in Colorado*. (Denver: Univ. of Denver Bur. of Bus. and Soc. Research. 1948. Pp. iv, 51, mimeo.)
- LINTNER, J. *Mutual savings banks in the savings and mortgage markets*. (Boston: Harvard Univ. Grad. School of Bus. Admin. 1948. Pp. xi, 559. \$6.50.)
- O'HARA, J. L. *Money and banking*. (New York and London: Pitman. 1948. Pp. xx, 671. \$4.75.)
- Banking statistics—recommendations on scope and principles of classification*. Report of the Sub-Committee on Banking Statistics of the League of Nations Committee of Statistical Experts. (New York: Columbia Univ. Press. 1948. Pp. 42. 25¢.)

Business Finance; Investments and Security Markets; Insurance

- BURTCHETT, F. F., and HICKS, C. M. *Corporation finance*. Rev. ed. (New York: Harper. 1948. Pp. vii, 712.)
- DAUTEN, C. A. *Business finance*. (New York: Prentice-Hall. 1948. Pp. xiii, 551. \$6.35; text ed., \$4.75.)
- MCCORMICK, E. T. *Understanding the Securities Act and the S.E.C.* (New York: American Book. 1948. Pp. 335. \$7.50.)
- Capital formation under free enterprise*. (New York: Nat. Assoc. Manufacturers. 1948. Pp. 88. Apply.)
- Compendium of official life insurance*. 60th annual ed. (Philadelphia: The Spectator. 1948. Pp. 309. \$12.)
- More inflation: how to protect your savings with common stocks*. (New York: Standard & Poor Corp. 1948. Pp. 165. \$10.)
- Spectator insurance year book, 1948-49 (corrected to August 1, 1948)*. 76th annual issue. (Philadelphia: The Spectator. 1948. Pp. 992. \$50.)
- A study of ownership of corporations in Hawaii*. (Honolulu: Hawaiian Econ. Foundation. 1948. Pp. 35.)

Public Finance

- BUEHLER, A. G. *Public finance*. New 3d ed. (New York: McGraw-Hill, 1948. Pp. xiii, 740. \$5.)
- COHEN, R. N. *The financial control of education in the consolidated city of New York*. With special reference to interrelations between the public school system, the municipal government, and the state. (New York: Columbia Univ. Teachers College. 1948. Pp. xi, 212. \$3.)
- JOYCE, S., and KILCULLEN, R. *The federal income tax; a guide to the income tax provisions of the International Revenue Code, the income tax regulations and the more important code decisions*. (New York: Clark Boardman. 1948. Pp. 359. \$6.)
- LINDHOLM, R. W. *Introduction to fiscal policy*. (New York: Pitman. 1948. Pp. 248. \$2.75.)
- MONTGOMERY, R. H., and others. *Montgomery's federal taxes—corporations and partnerships, 1948-49*. Vol. I, *Gross income and deductions*; vol. II, *Taxes, returns and administration*. (New York: Ronald Press. 1948. Pp. 885. \$20.)
- MONTGOMERY, R. H., and WYNN, J. O. *Montgomery's federal taxes—estates, trusts and gifts, 1948-49*. (New York: Ronald Press. 1948. Pp. 1277. \$10.)

NOTES

The following have been appointed members of the American Economic Association nominating committee for the current year: Simeon E. Leland, Northwestern University Chairman, James K. Hall, University of Washington, Margaret G. Reid, University of Illinois, Lloyd G. Reynolds, Yale University, Edward C. Simmons, Duke University, and Wolfgang F. Stolper, Swarthmore College. The chairman of this committee would appreciate receiving any suggestions for officers for next year as soon as possible.

The Sixty-second Annual Meeting will be held in New York City, December 27-30, 1949, with headquarters at Hotel Commodore. President Howard S. Ellis, of the University of California, would be glad to have suggestions from the members of the Association with regard to subjects for the program and persons qualified to present them.

BOOKS AND JOURNALS FOR EUROPEAN ECONOMISTS

Miss Mabel Newcomer, chairman of the Committee for Providing Aid to European Scholars, reports that there are many unsatisfied requests for books and copies of economic journals by libraries and universities. She requests that members of the Association make further contributions of books and journals as soon as possible. They should be sent to her, Department of Economics, Vassar College, Poughkeepsie, N.Y.

Necrology

Bernardo Cevallos, Date not known.

Fred E. Clark, November 26, 1948.

Bert C. Fuller, March 29, 1948.

William A. Frame, December 21, 1948.

Charles W. Gerstenberg, September 15, 1948.

Thomas W. Lamont, February 2, 1948.

James McC. Mitchell, October 14, 1948.

Gerald Morgan, October 13, 1948.

Homer N. Sweet, May 18, 1948.

Appointments and Resignations

Charles W. Anrod has been appointed associate professor of economics at Loyola University, Chicago, Illinois.

Frederick C. Armstrong has been appointed instructor in economics at Michigan State College.

Henry B. Arthur has resumed his duties as economist with Swift and Company after having served as chief of the Office of Program Review and Recovery Progress in the Paris office of the Economic Cooperation Administration.

L. Jay Atkinson was appointed lecturer in economics for the winter term at George Washington University.

Mary Lee Bodwell has been appointed assistant professor of agricultural economics at Michigan State College.

Arend E. Dör has been promoted from associate professor to professor of commerce at the University of Pittsburgh.

Leon A. Bosch has been promoted to professor of business administration in the School of Commerce, Northwestern University.

M. Bronfenbrenner, of the University of Wisconsin, has been awarded a World Area Training Fellowship by the Social Science Research Council for study of postwar reconstruction in Japan and plans to spend the academic year 1949-50 engaged in field work in Japan.

Robert E. Carmody is an instructor in economics at Loyola University, Chicago, Illinois.

Charles F. Carson was appointed professorial lecturer in economics for the winter term at George Washington University.

D. R. Cawthorne was appointed head of the department of economics at Miami University, Oxford, Ohio, effective September, 1948.

Gabriel F. Cazell, formerly of American University, is now professor of economics at Kalamazoo College.

John M. Clark, of Columbia University, was awarded the degree of Doctor, *honoris causa*, by the University of Paris in November, 1948.

Richard M. Clewett has been appointed assistant professor of marketing in the School of Commerce, Northwestern University.

Erwin B. Cochran has been advanced in rank from assistant professor to associate professor of accounting at Baldwin-Wallace College.

Camille W. Cook has been appointed instructor in business law in the department of economics and business administration at the Alabama Polytechnic Institute.

Morris A. Copeland has resigned from the Board of Governors of the Federal Reserve System and returned to teaching at Cornell University as professor of economics.

Richard Donham has resumed teaching as professor of business administration in the School of Commerce, Northwestern University, after several years of business.

James S. Earley, professor of economics at the University of Wisconsin, has been granted leave of absence for the current semester.

Clarence W. Fackler, professor of accounting at the School of Commerce, Accounts and Finance, has been promoted to assistant dean of the Graduate School of Business Administration, New York University.

W. A. Flinn has been appointed instructor in economics in the School of Business Administration, Emory University.

Dascomb R. Forbush has been appointed assistant professor of business economics in the School of Commerce, Northwestern University.

Charles D. Forrest has been appointed assistant professor of advertising in the School of Commerce, Northwestern University.

Harold G. Fraine has resigned as assistant director of research for the Joint Committee on Investment Research of the American Life Convention and Life Insurance Association of America to accept a position as professor of commerce in the School of Commerce, University of Wisconsin.

Walter Froehlich has been promoted from associate professor to professor of economics in the College of Business Administration in the Graduate School, Marquette University.

Frank H. Gane has been promoted to associate professor of finance in the School of Commerce, Northwestern University.

Paul R. Gawthrop has been appointed instructor in economics in the department of economics and business administration, Marietta College.

Roy E. Geeting is now teaching in the department of economics, University of Tampa.

Milton Gilbert is on leave from the Department of Commerce to serve as director of the research and budget department of the American-Jewish Joint Distribution Committee in Paris.

Joseph M. Gillman is associate professor of economics and business administration, and head of the department of economics at Suffolk University.

Melvin L. Greenhut has joined the staff of the department of economics and business administration, Alabama Polytechnic Institute, as assistant professor of finance.

Gertrude Grodski has been appointed assistant professor of economics at Loyola University, Chicago.

Cyril Haas has been appointed lecturer in economics at the University of Miami.

Kenneth B. Haas has been appointed professor of marketing at Loyola University, Chicago.

William Haber has resumed teaching at the University of Michigan after a year's service as special adviser on displaced persons to General Lucius Clay.

Jean C. Halterman has been appointed instructor in business organization and management in the College of Business Administration, University of Nebraska.

Abram L. Harris, of Howard University, has become associate professor of economics at the University of Chicago.

O. E. Heskin has returned to the University of Florida as head of the department of economics.

Hans Heymann has been appointed visiting professor of economics and foreign affairs at the University of Illinois for the current academic year.

Paul L. Howell has resigned from the School of Commerce, Northwestern University, to accept an associate professorship in finance at the School of Commerce, Accounts and Finance, New York University.

E. Jay Howenstine, formerly economist in the Office of Historian, UNRRA, has been appointed member of the economic section of the International Labour Office, Geneva.

H. J. Hudek, formerly of Iowa State College, has been appointed associate professor of economics at the Alabama Polytechnic Institute.

Holland Hunter has been appointed assistant professor of economics at Haverford College.

George B. Hurff has joined the staff of the University of Florida as research economist and associate professor in the bureau of economic and business research.

Leonid Hurwicz has returned to Iowa State College after spending a year with the Economic Commission for Europe of the United Nations, at Geneva, Switzerland.

Nathaniel Jackendoff, formerly of the University of Illinois, has been appointed assistant professor of economics at Washington and Jefferson College.

George Jaszi was appointed lecturer in economics for the winter term at George Washington University.

Eliot Jones, of Stanford University, is visiting professor of economics at the University of Washington during the spring quarter.

Jacob J. Kaplan has resigned from the Department of State to become a research associate, Institute of International Studies, Yale University.

Harold Kelso has been appointed professorial lecturer in business administration at George Washington University.

Willis R. Knight has been promoted to assistant professor of agricultural economics at Michigan State College.

Robert J. Lampman is assistant professor of economics at the University of Washington.

H. David Maloney has been appointed instructor in economics at DePauw University.

Daniel Marx has been granted a leave of absence from Dartmouth College to serve with the Economic Cooperation Administration in Paris.

C. Arnold Matthews has been appointed assistant professor of finance at the University of Florida.

Donald J. May is on leave from Emory University to continue his graduate work at the University of Chicago.

E. M. McCracken has recently been appointed controller of the University of Miami, Florida.

John B. McFerrin has been appointed head of the newly organized department of business organization and operation at the University of Florida.

Erskine W. McKinley, formerly of Birmingham-Southern College, has been appointed assistant professor of economics at the Alabama Polytechnic Institute.

Stewart Y. McMullen has been promoted to professor of accounting in the School of Commerce, Northwestern University.

Herman L. Meyers was appointed lecturer in economics for the winter term at George Washington University.

T. A. Mogilnitsky has been appointed chairman of the department of economics at Loyola University, Chicago.

Grady L. Mullennix has been appointed instructor in economics at the University of Texas for the current academic year.

Grover A. J. Noetzel, professor of economics at the University of Miami, Florida, has been appointed dean of the School of Business Administration.

Hugh Norton has been appointed instructor in economics at the University of Maryland.

Drakon B. Odom has been appointed instructor in accounting at the University of Florida.

Vincent A. Perry, formerly of New York University, has been appointed instructor in finance at Lehigh University.

J. Marvin Peterson has resigned from Miami University to accept a position with the Federal Reserve Bank of Minneapolis.

George S. Petras is an instructor in economics in the College of Business Administration of the University of Georgia.

Earl Phillips has joined the faculty of the School of Business Administration, Emory University, as instructor in business law.

Ronald M. Reifler has been appointed instructor in economics and statistics at Claremont Men's College.

Edward E. Rennhack has been appointed instructor in accounting in the School of Commerce, Northwestern University.

L. P. Rice has resumed his teaching at Dartmouth College after a semester's leave of absence.

Merrill J. Roberts has been appointed assistant professor of transportation and economics at the University of Florida.

Orville W. Roberts has been appointed professor of industrial management in the School of Commerce, Northwestern University.

Ned H. Scott has been promoted from teaching assistant to instructor in accounting at the University of Florida.

Stanley J. Seimer has been appointed instructor in industrial management in the School of Commerce, Northwestern University.

William B. Seiniger has been appointed lecturer in business organization in the School of Business Administration of the University of Buffalo.

Shou Shan Pu was a lecturer in economics at Michigan State College during the summer and fall quarters of 1948.

Louis Shere has been appointed professor of economics and director of tax research in the department of economics, Indiana University.

Emil G. Spitzer, of the International Monetary Fund, has been appointed lecturer in economics at the Catholic University of America.

John S. Spratt, on leave of absence from Southern Methodist University, has been appointed instructor in economics at the University of Texas for the current academic year.

Robert M. Strahl has resigned from the University of Nebraska to accept an appointment as associate professor of marketing at the University of Tennessee.

George W. Summerhill, formerly comptroller of Baylor University, has been appointed assistant professor of accounting at the University of Florida.

Robert P. Terrill has left his post as adviser on commercial policy in the Department of State to serve as deputy counselor of embassy, economic affairs, in Paris.

Carey C. Thompson is on leave from the University of Texas to pursue graduate work at the University of North Carolina.

E. T. Towne has retired from duty as a member of the faculty and as dean of the School of Commerce, University of North Dakota.

Myron H. Umbreit has been promoted to professor of economics in the School of Commerce, Northwestern University.

R. Miller Upton has been promoted to assistant professor of finance in the School of Commerce, Northwestern University.

Edward T. P. Watson has been appointed assistant professor of business administration in the School of Commerce, Northwestern University.

Murray L. Weidenbaum has been appointed research economist in the Department of Labor of the State of New York.

Lawrence W. Witt has been promoted to professor of economics at Michigan State College.

John A. Wolfard has been appointed associate professor of economics at the University of Utah.

VACANCIES AND APPLICATIONS

The Association is glad to render service to applicants who wish to make known their availability for positions in the field of economics and to administrative officers of colleges and universities and to others who are seeking to fill vacancies.

The officers of the Association take no responsibility for making a selection among the applicants or following up the results. The Secretary's Office will merely afford a central point for clearing inquiries; and the *Review* will publish in this section brief descriptions of vacancies announced and of applications made. It is optional with those submitting such announcements to publish name and address or to use a key number.

Communications should be addressed to: The Secretary, American Economic Association, Northwestern University, Evanston, Illinois.

Vacancies

Money and credit, corporation finance, statistics: Wanted by an Eastern university, man with Ph.D. or doctoral requirements substantially completed, with specialization in these fields. Rank and salary dependent upon applicant's qualifications. P135

International economics, principles, statistics: Wanted, by a well-established Eastern men's liberal arts college, a teacher for international economics, principles, and statistics. To start in September, 1949. Opening is for instructor with salary range of \$2,600 to \$3,000 or for assistant professor from \$3,100 to \$3,700. Master's degree needed for instructorship. Doctorate or near doctorate plus some successful teaching experience for assistant professorship. P136

Economists Available for Positions

Economic principles, public finance, corporate control, banking, investments, and accounting: Man, married, 44, Ph.D., University of Missouri. Sixteen years of successful college teaching; business experience in banking and production work; lieutenant commander, U.S.N.R. Now chairman of social science division and professor of economics in medium-sized, state-supported college. Prefers straight teaching position but would consider combination of teaching-administration work; salary and rank commensurate with responsibilities of the job; prefers Middlewest or West Coast location. Available in September, 1949. E156

Theory, money, cycles, integrated courses: Man, 39, Ph.D. Thirteen years of broad teaching experience, including management courses and some history as well as economics; some experience as an administrator and as a research consultant. Published articles; book to be published soon. E180

Economic principles, labor economics, money and banking, public finance and economic history: Man, 34, married, completing doctoral dissertation. Government economist and teaching experience in courses listed; now head of department in Eastern college. E214

History of economic thought, labor economics, marketing, principles of economics, world trade, industrial management: Man, 30, married, Litt.M. in Economics, working toward Ph.D. Three years of teaching subjects listed above in small Midwestern college; now head of school of business administration, rank of associate professor. Available in September, 1949. E225

Labor (economics, problems, law), economic theory, American economic history, business cycles, statistics: Man, 28, married, M.A., now working on Ph.D. dissertation at Columbia University. One year teaching at major college in New York; 3 years of executive experience in government industrial relations research and labor disputes settlement; 2 years of government administration and research in war materials procurement; sometime assistant in economics at leading university; research aide in labor relations for national business magazine. Available in June, 1949. E232

Economics and business administration: Man, 45, M.A., near Ph.D. Major field marketing but has taught a wide range of economic and business subjects; 17 years of college and university teaching, much of this time as head of departments of

NUMBER THREE

A CRITICISM OF THE HAVANA CHARTER

By SIR HUBERT HENDERSON*

In their bulk and mass, the International Trade Charter and the Organization which is to administer it resemble a mountain rather than a mouse. Yet the significance and value of what has been achieved with such prolonged and expensive toil are far from clear. The basic principles which the Charter was originally intended to express and to enforce are wrapped up and swaddled in thick layers of exceptions and saving clauses, through which it may be hard for them to penetrate. Nor, speaking generally, is it possible to blame those who have insisted on the exceptions and saving clauses. The basic principles, it is increasingly manifest, could not possibly be applied immediately. Accordingly, the prevailing disposition among supporters of the Charter is apparently to stress its negative value as a restraint. Progress towards the goal of a nondiscriminatory, freely working international economy cannot, it is reluctantly conceded, be made just now; it may even be necessary to acquiesce in various movements in the opposite direction. But such retrograde movements must be carefully controlled and kept within the limits which circumstances really justify. This, it is claimed, is a function of great importance; and for it the International Trade Charter and the Organization are supposed to be well contrived.

This is so modest a claim that it may seem ungracious to question it. Yet I feel obliged to record my fear that the Charter may do more harm than good and may prove more of a hindrance than a help to the creation of a healthy international economy. The harm, it is true, may not be very great, and will mostly be of a less immediately tangible sort than there was once reason to apprehend. Countries to which import restrictions are indispensable in order to correct a large deficit in their balance of payments will not be debarred from effective action

* The author is Drummond professor of political economy in the University of Oxford.

by their Charter undertakings. For these and many other contingencies, the exceptions and saving clauses make what should be adequate, though by no means wholly satisfactory, provision.

None the less, the question is pertinent whether the basic principles of the Charter are really sound and wise. Is the present difficulty of applying them only a transient one? Or does it spring from the fact that these principles are fundamentally ill-suited to the conditions and problems of the modern world? If the latter is true, the consequences of proclaiming them as the goal of policy are bound to be unfortunate. At the least, we must expect disillusionment, cynicism, a sense of frustration and considerable prejudice to the idea of international co-operation. On unfavourable hypotheses, there are more serious dangers to be feared in the years that lie ahead—friction and recrimination, charges of bad faith on the one hand, and undue interference on the other, bedevilling the relations between friendly countries and Anglo-American relations in particular.

The Principles of the Charter

Certainly, if such risks are to be avoided, it seems to me important that what I have called the basic principles of the Charter should be discussed far more freely, critically and objectively than has been customary hitherto. In the lengthy process of semi-official exchanges and fully official conferences which preceded the signing of the Final Act at Havana, discussion of these principles upon their merits played no part. They were a *chose jugée*. The principal governments concerned were already committed to them by the terms of the various Mutual Aid Agreements. It was only the manner in which they should be applied that was still open to argument.

The course of public discussion has been much affected by the same inhibition. British opinion especially has been influenced by a desire to avoid the impropriety of seeming to challenge principles to which we are committed. This reluctance is increased by considerable uncertainty and confusion upon the merits of the case. On the one hand, the principles in question do not seem to square with the policies which it is necessary to pursue. On the other hand, they are in full accord with a long established national tradition which still makes a wide appeal.

Confusion is indeed the chief characteristic of such discussion of the principles as has taken place. It is remarkable how seldom the arguments of the disputants seem to meet. This reflects, in my opinion, a deep confusion of thought in the principles themselves. Desirable aims are mixed up in them with false inferences and unwise behests; and I think it of real importance to try to disentangle them. The desirable aims may be formulated as follows: (a) a large and expanding

volume of international trade, which will permit the fullest possible realization of the advantages of an international division of labour; (b) as a condition of the foregoing, the utmost practicable scope for the processes of triangular or multi-angular trade and payment; (c) commercial policies which satisfy the desire for equity and fair-dealing between nations.

To these aims all sections of British opinion subscribe wholeheartedly and without reserve. It is a commonplace that Britain is far more vitally dependent on imports than any other country of comparable size. The ampler the dimensions of world trade as a whole the easier are we likely to find it to maintain the large external trade that is essential to us. We certainly desire conditions under which we can use exports to one market to defray imports from another, and thus avoid the need for a precise balancing of accounts with each country with which we trade. No country has better reason than Great Britain to fear the spread of "autarkic" ideas throughout the world, or to welcome the establishment of a code of international good behavior which would restrain arbitrary self-regarding acts of national policy injurious to the interests of others.

It may seem only a short step from these propositions to the principles of the Havana Charter, which may be summarized thus:

1. Non-discrimination;
2. Reduction of tariffs on the basis of reciprocal concessions;
3. Subject to a long series of reservations, the outlawry of import restrictions; to which should be added, though it appertains strictly to Bretton Woods, rather than Havana:
4. Free convertibility of currencies.

At first sight, admittedly, these seem appropriate means for achieving the accepted ends. How can international trade be enlarged unless trade barriers are reduced? Are not import prohibitions and restrictions usually the most drastic type of trade impediment, and the one which lends itself most readily to abuse by high-handed application? How can triangular trade be developed without facilities for exchanging one currency for another? What causes more ill-feeling or conflicts more obviously with the instinct of fair-play than discriminatory treatment? Surely, then, the Havana principles are proper ones to proclaim and press, provided that the detailed obligations make due allowance for the difficulties of applying them. All this is plausible, undoubtedly, but in my view it is seriously misleading.

It is misleading because the list of desiderata given above is incomplete. This list omits equilibrium in the balance of payments. The unhappy international economic story of the interwar period, the scarcely more promising experience of the last few years, both show that this is a requirement of paramount importance. Nor is it one which is ade-

quately met by the technique of escape clauses and exceptional provisions. Disequilibrium in the balance of payments is the central problem of modern international economics. No expansion of international trade can be soundly based, nor, therefore, can it prove enduring, unless this far-reaching disequilibrium has been overcome. This is indeed the chief task that confronts international economic statesmanship today, as also European statesmanship and the national statesmanship of many countries. It is a task, moreover, which calls pre-eminently for constructive action.

Non-Discrimination

There could be no more impressive recognition of this truth than that contained in the Marshall Plan. The central features of this plan are, first, the generous provision of dollar aid over a limited period of years, and second, the promotion of greater economic cooperation between the countries of Europe. The latter objective comprises in its turn two elements: appropriate financial arrangements, including aid from the relatively strong to the relatively weak, and the development of intra-European trade. Now this last policy embodies a principle which is very different from that of nondiscrimination. In effect, the Marshall plan says to the embarrassed countries of Europe: "You are finding it difficult to buy all the things you need from the United States. Well, we are prepared to help you for a time, in so far as you really need our help. But you must reduce your calls on us to a minimum. In particular, you must not look to the United States for supplies which you might obtain from one another without much difficulty." On the other hand, the principle of nondiscrimination says in effect: "You must not buy from one another (unless indeed you go so far as to form a Customs Union) goods that you might obtain from the United States or elsewhere at a slightly cheaper price."

There is a contradiction here which seems to me more fundamental and more significant than is commonly admitted. It is true, of course, that the Havana Charter virtually exempts countries which are in serious balance-of-payments difficulties from the restraints of the non-discriminatory obligation, so long as these difficulties remain. And it can be argued without any logical incoherence that this obligation will become appropriate and desirable under "normal" conditions, when these difficulties are supposed to have disappeared. But it is precisely this sharp distinction between the exceptional and the normal which is fundamentally unreal. The restoration of basic equilibrium in the international balance of payments is no mere passing problem of the transition from war to peace. It is a long-term, large-scale task. Actual balance-of-payments deficits must, it is true, be eliminated, willy-nilly,

fairly soon; and disagreeable measures, including drastic import programmes and discriminatory trade arrangements may be needed in many countries for this purpose. But it may be no less necessary to retain such measures, however modified, for many succeeding years, to prevent these deficits from reappearing.

Again, it is true that by forming a Customs Union or free-trade area, or by making an "interim agreement" designed to lead to either of these things, European countries can obtain leave to discriminate permanently in favour of each other. In thus distinguishing between Customs Unions and preferences, the Havana Charter is, of course, in full accord with tradition; the same distinction used to be recognized in the application of the old-fashioned most-favoured-nation clause. The justice of this distinction has, however, long been doubtful. The members of a Customs Union discriminate much more decidedly in favour of each other, as against the outside world, than do the parties to a preferential trade arrangement. It is far from clear why it should be equitable and praiseworthy to practise discrimination in an extreme degree, but inequitable and reprehensible to practise it in a moderate degree. The distinction may be defended by various arguments resting on the plane of practical convenience, but its ethical basis is not easy to discern.

It is a distinction, moreover, which does not fit modern problems and modern facts. Benelux notwithstanding, a genuine Customs Union, in the sense in which the term has been understood in the past, is quite impracticable in the Europe of today. In many countries, import policy has now become, and is likely to remain, one of the main and most vital functions of government. In Great Britain, for example, the standard of living that can be enjoyed immediately, and on the other hand, the prospect of overcoming our balance-of-payments difficulties and maintaining our monetary reserves depend very largely on the rate of expenditure on imports of different commodities from different sources; and this is regulated by our governmental import programmes. This is not a function which the British government could allow to pass outside its effective control. Nor, I suggest, could the government of any other country which is faced with similar difficulties, and which intends to keep any substantial measure of independence. The idea of forming an effective free-trade area, with a uniform treatment of imports from countries outside it, is only really feasible between countries that are prepared to unite politically, and to unite, not in a loose federation, but under a highly centralized form of government.

This truth, however, is not yet as manifest as I believe it will become. Although any full Customs Union is clearly impracticable in

Europe for the time being, it is easy to cherish illusions that the obstacles may eventually be surmounted. It might even be possible, though in practice it would not be easy, to make early progress in adjusting tariff rates towards the requirements of a Customs Union, and to lean more heavily for the essential work of regulating imports on quantitative restrictions, assumed to be an emergency expedient. It may well be, therefore, that the Charter will serve to stimulate arrangements claiming to be "interim agreements" within the meaning of Article 44. In considering whether such claims are justified, the Organization will presumably adopt extremely tolerant standards, under the influence of the prevalent idea that any arrangements of this type represent a desirable development conducive to the general cause of European unity.

For my part, I doubt whether this idea is justified. It is certainly of the utmost importance to develop intra-European trade and to secure a "closer integration" between the economies of different European countries. But it is premature to suppose that we know today at all precisely how these ends can best be served. Arrangements that are really helpful must be highly flexible. To try to force them within the framework of a project for a Customs Union may well prove profoundly unwise. It may lead to subsequent deadlock and breakdown, injurious to the larger cause, which might have been forwarded by less ambitious arrangements. It is almost certain to involve an immense amount of make-believe and casuistry, corrupting to those who take part in it, and exasperating to others. Indeed, if any "interim arrangements" are approved, and a serious attempt is made to enforce the nondiscrimination rule elsewhere, countries which find themselves hampered by it will have good reason to complain that the dice are loaded against them.

Here I may observe that in British eyes the dice of the nondiscrimination rule seem already to be loaded against the preferential system of the British Commonwealth. A Customs Union between Great Britain and the Dominions is clearly impracticable; and no "interim agreement" could be made between them purporting to lead to this. But that is not all. Article 15 permits, subject to certain conditions, the establishment of new tariff preferences between countries which "are contiguous one with another" or which "belong to the same economic region." No such possibility is open to the countries of the Commonwealth which are separated by the oceans. Here the Havana Charter departs from tradition; for preferences between countries belonging to the same political system (and after all the British Commonwealth, despite the looseness of its formal structure, is an association which has stood the test of two world wars) were not regarded as violating the most-favoured-nation clause.

It is scarcely an exaggeration to say that the reduction of tariff preferences within the British Commonwealth is the only consequence of the Charter which is definite and certain. I appreciate the strength of the objections of American opinion to the arrangements of the Ottawa Conference of 1933. None the less I find it difficult to understand what useful purpose can be served by a reduction of Imperial Preference in the altered circumstances of the present day. Its maintenance, and where desirable its extension, could do no real injury to American export trade; for the Commonwealth will always be ready and anxious to import from the United States to the full extent of the dollars it can earn both directly and indirectly by export to other markets. On the other hand, the reduction and restriction of these preferential arrangements must tend in some degree to make it more difficult to restore and maintain equilibrium in the balance of payments between the sterling and the dollar areas.

The Reduction of Tariffs

I have already indicated my opinion that one of the main weaknesses in the philosophy which underlies the Charter is the distorted perspective in which it views the problem of balance-of-payments equilibrium. This should be recognized as a key objective; it should be a primary purpose of economic policy, both national and international, to establish and maintain it; and the provisions of the Charter should have been largely directed to this end. In fact, the Charter treats this vital matter in an essentially passive way. It takes it for granted that the balance of payments will normally be in equilibrium, and thinks it sufficient to concede, almost by way of afterthought, that when countries are threatened by serious deficits they may be allowed to indulge in practices which would otherwise be forbidden to them.

This misconception vitiates the approach to the problem of reducing tariffs. The Charter contemplates that tariffs should be reduced by negotiations between particular countries, based on the principle of reciprocal concessions. This, of course, is the fundamental principle of the American Trade Agreements Act; and it is easy to understand, in the light of the history of the measure, supported as it has been by the low-tariff and criticised by the high-tariff school of thought, that substantial tariff reductions could not be effected at present in the United States on any other basis. This, however, does not alter the fact that the principle in question ignores the possibility of a serious balance-of-payments problem, and is therefore ill-fitted to serve as the basis of international economic policy in the world of today.

Here again indeed there is a fundamental contradiction which is insufficiently appreciated. The principle of reciprocal concessions comes very near to saying that tariff reductions, calculated to increase Ameri-

can imports, can only be made in return for tariff concessions by other countries, calculated to increase American exports by an equivalent amount. This, in turn, comes very near to making it a *sine qua non* of tariff reductions that they should do nothing to solve the dollar problem or to readjust the balance of payments of the world. In practice, doubtless, the principle will be interpreted and applied more reasonably. None the less, it must serve as an obstacle to the rearrangements that are urgently desirable.

The true logic of the problem can be stated in a simple syllogism. To secure a balanced international economy, it is essential that the United States should increase her import purchases by much more than she increases her export sales. Therefore she should be ready to reduce her import duties, although other countries may find it necessary to maintain and even to increase theirs. More generally, it should be for countries to reduce their tariffs and encourage imports, not in proportion to the reciprocal concessions they are able to secure, but in proportion to the strength of their balance-of-payments position.

This, I submit, is one of the main principles on which a wise code of international good behaviour should be based. Doubtless it is still far removed from the region of acceptability to American opinion. Yet the logic behind it is so strong, and is likely to be driven home so insistently by the lessons of events, that I am not without hopes that it will gradually win an increasing measure of recognition and acceptance in the years that lie ahead. To this process, unfortunately, the embodiment of the opposite principle in the Havana Charter must be an obstacle.

In the meantime, it is important to note one influence which the treatment of tariff reductions in the Charter must be expected to exert. It is likely to stimulate and to prolong the use of quantitative import restrictions. If countries that find it necessary to curtail their expenditure on imports are unable to raise import duties for this purpose, they will rely increasingly on the alternative technique of quotas. This will be a paradoxical, and it may be a somewhat unfortunate, consequence. As will soon become clear, I do not personally share the extreme dislike of the quantitative method which forms a main element in the philosophy of the protagonists of the Charter. On the contrary, I believe that concrete or quantitative regulation is likely to play an important part in international economic life for a more or less indefinite future. For many commodities, however, imports are better regulated by duties than by quotas; and it is possible that for some commodities a combination of the two methods would be the most satisfactory arrangement. It is undesirable from every point of view to force the use of the quantitative method. Yet this may well be an

unintended result of the provisions of the Charter. If so, it will be attributable to the false assumption that import restrictions can be abolished altogether at an early date.

Quantitative Regulation, Exchange Rates and the Price System

As it emerged finally from the Havana Conference, the Charter allows quantitative regulation in so many different forms and for so many different purposes as to obscure the fact that the original intention was to prohibit the use of this method, save in the most exceptional circumstances. It is under this heading more than any other that exceptions and escape clauses were multiplied during the long-drawn negotiations that preceded the Final Act; and in practice, as I have just suggested, the Charter may well do more to stimulate than to check the spread of quota restrictions. It remains true, none the less, that in the minds of those who have done most to initiate and to push forward the project of the Charter, a strong dislike of quantitative regulation, as something inconsistent with, and inimical to, a self-adjusting price system, has played throughout a prominent part. It is, I think, more useful to consider the broad issue of economic policy which arises than the detailed provisions of the Charter relating to quantitative regulation.

The position from which I approach this question may be stated summarily as follows. When there are no large maladjustments that must be corrected, or no large readjustments that must be made, the economic system can be entrusted to the forces of the price system with the prospect of reasonably satisfactory results. But in any situation which calls for large-scale readjustment, it is necessary to supplement and sometimes to supersede these forces by more direct measures, consciously directed to the object which has to be attained. The forces of the price system are strong enough to effect small adjustments smoothly; but when the work they have to do is large, they are apt to prove clumsy, wasteful and ineffective.

As a special case of this general rule, countries in balance-of-payments difficulties must use the direct method of quantitative regulation to limit their expenditure on imports, and also apply appropriate measures of control to promote their export sales. That this may be necessary, as a strictly temporary expedient, is not now seriously disputed, even by those whom I call for convenience the ideologues of the price system. But many of them take the line that no difficulties can justify the continuance of such expedients for a prolonged period. If the maladjustment continues for several years, in the sense at least that it would reappear if the direct controls were removed, this proves, they would argue, that there is something radically wrong in the under-

lying price relations of the country concerned; and they believe that if this error were corrected, the maladjustment would disappear fairly soon. In other words, they concede that direct controls may be useful as a stop-gap; but insist that the work of readjustment must be taken over as soon as possible by price-system correctives. The particular corrective which appears to be most fashionable at the moment among adherents of this school of thought is the depreciation of exchange-rates.

This is a point of view which appeals especially to academic economists, who are tempted by a semi-aesthetic appreciation of the harmonious inter-relations of the price system, as pictured by theoretical analysis, to exaggerate its actual virtues. It represents the essence of the answer which some would give to many of the arguments I have used in the course of this article. They would readily agree, for instance, that equilibrium in the balance of payments is no less important than the expansion of international trade. But they would argue that the former object can only be secured by establishing proper price relations through such means as the adjustment of exchange-rates, and that tariffs, import restrictions or other trade impediments, though they may be of some temporary help as a stop-gap, can be no substitute in the long run for correct price relations. Therefore, they would conclude, it is right to concentrate on lowering trade barriers, and in particular on eliminating quantitative restrictions as soon as possible.

Such arguments have an appearance of profundity, which in my view is misleading. It is always important, I agree, to secure price relations which will help rather than hinder any readjustment which has to be made. It does not follow that price relations can be relied upon as the main active force for effecting the readjustment. In particular, there could be no more dangerous idea than that a depreciation of exchange-rates is the sovereign remedy for a balance-of-payments deficit. It is doubtless true that it is helpful to a country's balance of payments that its currency should be "under-valued" rather than "over-valued," though a high degree of "under-valuation" may be harmful. It is most rash to assume that the right degree of "under-valuation" can be brought about by lowering exchange rates. This must tend to raise internal costs, prices, and incomes; and since an inflationary movement is never easy to control, the ultimate result may be to raise internal prices to the full extent of the exchange depreciation. If the idea is that exchange-rates should then be lowered again, in the hope that next time the luck will be better, there is an obvious danger of a vicious spiral of internal inflation and devaluation. The recent experience of Italy and France shows that these are not fantastic pos-

sibilities. Nor should these object lessons have been necessary. The pertinent story of the nineteen-twenties should have been enough.

Of course, if internal inflation has led to a serious over-valuation of a country's currency, exchange devaluation may be essential. Indeed the recent fall of prices in the United States makes it probable in my opinion that it will prove necessary in the end to devalue sterling (together perhaps with other European currencies) relatively to the dollar; though it would be much better, if conditions permit, to defer this until *after* the inflationary trend in our own economy has been brought unmistakably to an end. It is vital, moreover, that any exchange-rate adjustments that are made should be once-for-all adjustments. The idea that frequently occurring exchange-rate variations might provide the regulating spring of an automatic international economy will not, I believe, stand up to critical examination; and the prominent part which it has come to play in modern price-system ideology is a most curious phenomenon. Before 1914, when an otherwise unregulated price system worked tolerably well, exchange rate stability was regarded as an essential feature of it; and it is still, in my opinion, an important desideratum.

Behind the practical dangers which would arise if an attempt were made to apply the new doctrine of exchange-rate variations, lies a more fundamental consideration. A country which has to adapt itself to straightened international means must readjust the structure of its economic life. It must alter its habits of consumption and production. Any necessary reduction of imports will be less injurious to its standard of life, if it is *selective*, falling heavily on some items and sparing others, than if it is indiscriminate. Therefore, a radical change in the composition of the country's imports may be needed. It is an illusion to suppose that such changes can be quickly brought about by price-system forces of any type, unaided by direct controls. In a sense, it may still be true that the need for such controls may prove to be only temporary. It may not continue after the new production and consumption habits have become established, and the country's economy has been recast securely in a new and appropriate mould. But the time required for this is certainly far longer than any that the conception of a transitional postwar period is apt to suggest.

Moreover, it is not only for the work of readjustment that quantitative regulation may be needed. It may also be useful for the purpose of maintaining stability, of minimizing the vicissitudes and disturbances which are apt to occur in an unregulated economy. The experience of the interwar years shows how serious such disturbances may be, and how unsafe it is to rely on the price mechanism to prevent them.

This truth is indeed recognised in the Charter in a few applications. It concedes the legitimacy of import restriction, for the protection and development of certain types of infant industry; and it must be expected that extensive use will be made of this concession.

The chapter on Inter-Governmental Commodity Agreements is based on the proposition that for primary commodities there may be a "tendency towards persistent disequilibrium between production and consumption, the accumulation of burdensome stocks, and pronounced fluctuations in prices." Here, accordingly, the Charter gives some positive support to the idea of quantitative regulation in the form of "commodity control agreements" on an international basis, though it seems unlikely that many such agreements would succeed in practice in running the gauntlet of the elaborate procedure and the rules and principles of Chapter VI. Similarly, Bretton Woods makes provision for the permanent retention of exchange control for the purpose of regulating capital movements; and no one who recalls the mischief that was done in the interwar period by the large erratic scurries of "hot" money can seriously dispute the necessity of this control in a world which has lost its faith in the stability of exchange rates.

Economic instability, however, may arise from many different causes and may take many different forms; and there is a correspondingly large variety of circumstances in which it may be wise to apply direct controls to the external sector of a country's economy in the interests of steady and orderly development. It is foolish to suppose that these circumstances can be adequately provided for by any list of exceptions which is drawn up now. Such exceptions will be apt to emphasize the arbitrariness of banning direct controls in other circumstances in which it may come to seem more justifiable and important to employ them. I can see no escape from the dilemma that those provisions of the Charter which are directed against quantitative restrictions must either be treated as a dead letter, or will arouse a resentment so strong as gravely to prejudice the idea of international arrangements.

* * * * *

These are the reasons why I think it probable that the Havana Charter will do more harm than good. It is ill-related to the very difficult problems which exist and which loom ahead. The true aims of international economic statesmanship are in my view, first, to facilitate the large readjustments in the flow of international trade that are needed to restore equilibrium, and second, to ensure that readjustments are made in such a manner as to cause the minimum of avoidable injury and disturbance to the economic life of the world as a whole, and in particular to that of the United States.

At present the United States is generously providing large-scale financial aid to cover the deficits of Europe. It is very reasonable that Americans should insist that this arrangement cannot continue for very long. But the cessation of Marshall Aid implies an economic readjustment which must take the form, either of a greatly diminished demand for American exports, or a greatly increased importation of European or other goods into the American market, or possibly both; in any event, a large change in the import-export balance of the United States. If at the same time the sellers' markets of recent years are replaced by buyers' markets, the dangers of serious dislocation in the American economy are obviously great. It is urgently desirable that constructive thought should be directed to the problem of how these dangers can best be minimized, without obstructing the task of readjustment. This can only be done along very different lines from those of the Havana Charter.

INTERNATIONAL DISEQUILIBRIUM AND THE POSTWAR WORLD

By RAYMOND F. MIKESELL*

Classical international trade theory was concerned with the maintenance and restoration of international equilibrium through the pricing mechanism. The conclusion that such maintenance and restoration could in fact always be accomplished automatically through the pricing mechanism followed from the assumptions of free competition and the mobility and full employment of resources within each country. The absence of these assumed conditions, which were never fully realized, has made it necessary to consider states of international disequilibrium with respect to which corrective price adjustments are either prevented from taking place or would prove to be inadequate if they did take place.

Any attempt to classify disequilibrium as to types is dangerous because in any given disequilibrium situation more than one causal factor is almost invariably present. It may, however, be useful for purposes of analysis to differentiate between three types of disequilibrium situations: (1) those arising from disparities between internal and external prices and costs; (2) those arising from relative changes in the levels of national income at home and abroad; and (3) structural disequilibrium resulting from shifts in demand and supply conditions in internationally traded commodities or from changes in the invisible items in the balance of payments, which have not been brought about by changes in the relative levels of prices or incomes at home and abroad.

It will readily be admitted that any concrete situation may contain elements of more than one type of disequilibrium. Changes in relative levels of income in different countries are accompanied by relative price movements, while shifts in the structure of production and trade affect both prices and incomes. It is also difficult to determine which factors are *causal* in any given disequilibrium situation, in the sense that an appropriate adjustment of these factors would effect a cure. It may, for example, be found that relative movements in internal prices and costs have taken place but the removal of the disparities may have little effect on the trade balance because of the nature of demand and supply elasticities. Likewise, relative changes in the levels of national income may or may not have a significant effect upon

* The author is professor of economics at the University of Virginia.

trade balances, depending upon the nature of income elasticities of demand for the imports of the countries under consideration.

In considering the factors responsible for a given state of disequilibrium, it is important to distinguish between the problem of equilibrium for the group as a whole and for the individual country. Too often analysis has been confined to the problem of equilibrium for the individual country when perhaps the fundamental cause is to be found in the complex economic relationships among a larger number of countries. There are, of course, abundant cases in which small countries can take steps such as exchange rate devaluation or deflationary action to balance their international accounts without serious repercussions upon the international position of other countries. But where disequilibrium is widespread, corrective measures on the part of individual countries may fail to be effective in eliminating a general disequilibrium.¹ On the other hand, measures taken jointly by a group of countries may achieve beneficial results for the group as a whole which would not accrue to an individual country which undertook the same action unilaterally. For example, an individual country may find that an adjustment of its own exchange rate, all other rates remaining the same, would not materially affect its trade balance. A general adjustment of rates may, however, result in an expansion of trade among a group of countries with the result that the balance of payments problem of all members will be eased. This improvement might come about by reducing the dependence of all members of a particular group of countries on imports from a country whose currency was in relatively short supply. These same considerations with respect to the effects of actions of individual countries on other countries as a group will apply equally in cases of adjustments involving deflationary action or changes in the structure of production. Where disequilibrium is world-wide in character, corrective measures on a multilateral basis including planned alterations in the patterns of production and trade among a number of countries, may be called for. It is this type of disequilibrium situation which presents the most serious problem for the postwar world and with which this article is especially concerned.

The Disappearance of Automatic Correctives

In the decades since World War I, we have witnessed a gradual weakening or elimination of certain forces which in the past have operated to restore international equilibrium once it had been disturbed. The tendency on the part of treasuries and central banks to pursue

¹ For a discussion of the limitations of exchange depreciation for correcting general disequilibrium, see J. J. Polak, "Exchange Depreciation and International Monetary Stability," *Rev. Econ. Stat.*, Vol. XXIX, No. 3 (Aug., 1947), pp. 173-83.

internal monetary policies which are independent of changes in their holdings of gold and foreign exchange was observed in the 1920's and 1930's, and has now become almost universal. While this development tended to eliminate adjustments *via* the specie-flow-price mechanism, the widespread adoption during the 1930's of compensatory fiscal policies which offset decreases in incomes resulting from the emergence of trade deficits had the effect of preventing a restoration of equilibrium through changes in relative levels of money income among trading nations. Since the end of World War II, new interferences with the mechanism of international equilibrium have appeared, some of which may prove to be transitory, but others, depending upon the ultimate outcome of current trends in the character of economic institutions and trade practices among the nations of the world, may prove to be permanent. We may list a few of these developments as follows:

a. *Internal price and distribution controls, international commodity agreements and bilateral trading arrangements.* Such controls and agreements tend to insulate internal price systems from external forces. Changes in prices and in demand and supply conditions in one country are not permitted to have their normal effects on prices in other countries.

b. *The expansion of state trading.* Imports by state trading organizations are likely to be governed by the requirements of planned internal investment and consumption programs rather than by the operation of free-market forces. Likewise, export trade under state control, especially when accompanied by the allocation of resources for the export industries, may tend to be relatively unresponsive to world market conditions. When state trading is combined with bilateral trade agreements, the character of the trade will in considerable measure be determined by the requirements of the bilateral bargaining. For example, countries in a weak bargaining position may have to accept certain unessential or luxury commodities along with the more scarce items which they seriously need.²

c. *Unrealistic patterns of exchange rates.* Improper rates not only make it difficult or impossible for countries to achieve equilibrium without the use of controls, but they tend to direct trade and production for export into abnormal and uneconomical channels. For example, postwar intra-European trade has been characterized by a high proportion of trade in luxury products (where prices are generally uncontrolled) whereas such commodities should either move to the dollar area or not be produced at all. Exchange rates which do not reflect differ-

ences in prices and costs between countries also tend to encourage barter trade since normal commercial trade at existing rates becomes impossible.

d. *The existence of large international debts which must be serviced in gold or hard currencies.* Debt service payments represent an inflexible item in a country's balance of payments and make adjustments *via* the merchandise balance more difficult.

e. *The inability or unwillingness of nations to achieve internal price stability.* Many nations have plans for reconstruction and development programs which will require large annual capital outlays for the next decade or more. The constant pressure for higher wages and the demand for social reforms and betterment of the working classes may, however, mean a level of savings insufficient to finance such programs except by inflationary devices. Whether inflation is open, *i.e.*, accompanied by price rises, or suppressed, *i.e.*, accompanied by rationing and price controls, imports will be encouraged and exports discouraged and a balance will be difficult to maintain. Under inflationary conditions, either foreign exchange rates must be permitted to rise or import controls must be employed. Most governments, however, prefer controls to devaluation since devaluation increases the prices of essential commodities which in turn adds to the internal inflationary process.

f. *The almost universal adoption by governments of fiscal and monetary policies which seek to control the volume of monetary demand independently of the volume of monetary reserves and of the balance of payments.* The whole principle of automatic correctives rests on the assumption that internal monetary demand will be responsive to changes in the payments balance without deliberate interference on the part of the economic authorities. The existence of inflexible prices plus the power of trade unions to prevent wage reductions even in the face of unemployment, may require the monetary authorities to offset the effects of an adverse balance in order to avoid severe depression.

In the light of the above developments, it seems unlikely that automatic correctives will be available for maintaining a reasonable degree of international balance, even after the present structural maladjustments brought about by the war have been eliminated. Internal economic policies are likely to be determined primarily with reference to governmental planning considered necessary to achieve domestic objectives such as full employment, capital reconstruction and development, and higher living standards for the masses. Foreign trade and exchange policies must be adjusted to the needs of the domestic economy for carrying out these objectives. Under these circumstances, many nations may be unable to adopt foreign economic policies which

are consistent with a current international balance achieved without the use of controls.

The Significance of International Equilibrium

The concept of international equilibrium as it is generally used in economic literature is based on the classical postulates of a world in which economic decisions are made by free private enterprise operating without governmental interference, except for tariffs. The usual test of whether or not a country is in equilibrium is to determine whether total receipts from current transactions plus long-term capital imports are equal to total current payments plus long-term capital exports. A true equilibrium in the classical sense cannot exist if it is achieved by means of exchange and trade controls. But, in a country which maintains a high degree of internal economic controls, direct or indirect control over foreign trade is almost inevitable. A nation is not likely to nationalize its steel industry and permit free foreign trade in steel, nor is a nation which finds it necessary to allocate scarce materials among domestic producers likely to permit free foreign commerce in these scarce materials or the products manufactured from them.

The question arises as to what significance the concept of equilibrium has for controlled or partially controlled economies. In the case of state-controlled economies, we might define equilibrium in terms of internal and external cost-price relationships.³ Thus a nation would be in equilibrium if it purchases everything abroad which could be obtained at prices below domestic costs and exported everything not consumed at home at prices which covered domestic costs, provided total receipts and expenditures were equal after adjustment for long-term capital movements. It is theoretically possible for planning to achieve just this result, but this ideal has never been approached by planned economies either because the planners have been more concerned with non-economic ends or because of poor planning. One difficulty is that the government rather than the ultimate consumer may frequently make the decision to increase or decrease imports. Suppose, for example, that the government decides to expand its purchases of foreign capital equipment. In order to maintain equilibrium, shifts in internal production and in aggregate monetary demand would have

³ It should be pointed out that the political authorities in controlled economies may have non-economic ends which often conflict with economic ends such as the maximization of real national product, e.g., the carrying on of economic warfare or the liquidation of the Kulaks. Moreover, different economic ends may conflict. For example, efforts to secure a more equitable distribution of income for the purpose of maximizing welfare may conflict with the maximization of the national product in the future. Hence, in defining equilibrium for any given nation we would need to take into consideration both economic and non-economic ends.

to be made so that imports of consumption goods will be reduced or exports increased sufficiently to restore the balance without rationing and without violating price-cost ratios. In so-called "mixed" economies where the government controls investment in certain fields and hence imports of capital equipment, the problem of adjustment would appear to be even more difficult than in completely controlled economies.

A definition of equilibrium in terms of internal and external price-cost relationships is not likely to be very useful in dealing with immediate problems, although it has theoretical significance as an ideal for all countries to strive for. A practical concept of short-term equilibrium must take into account the organization of the particular economy under consideration and the economic objectives which the economic authorities have in mind.⁴ Thus in a relatively free economy the balance should be achieved with a minimum of trade controls. On the other hand, in a controlled economy one would expect controls on external trade which were consistent with internal controls and with the objectives of the planning authorities. If it were the policy of the economic authorities that the nation could not afford to consume certain luxury commodities, their importation as well as their domestic production would properly be forbidden. Or if the government decided to use a larger proportion of the nation's foreign-exchange receipts for imports of capital equipment and to direct consumer expenditures away from imports, appropriate controls might be employed.

How then shall we define short-term equilibrium for a controlled economy? It can only be defined in terms of some deliberate plan for the employment of the resources of the economy and the distribution of the product among the consumers. Presumably the economic authorities will determine certain production goals and certain standards of consumption consistent with the productive capacity of the country. We might define equilibrium for a controlled economy as a condition in which current foreign-exchange receipts were sufficient to pay for that volume of imports necessary to (1) carry out a production plan based on the most efficient use of existing productive resources and plant capacities in the light of consumption and investment goals, (2) achieve a predetermined program of investment, and (3) maintain a predetermined level and composition of consumption. The level of capital investment may be determined by the amount which the economic authorities believe is necessary to achieve equilibrium at some point of time in the future in the light of the consumption goals of the planning authorities, or it may be dictated by the requirements of military pre-

⁴ It must be kept in mind that these economic objectives may be dictated by underlying political objectives.

paredness. The consumption goals may be related to some historical or accustomed level or to that level which is believed to be the minimum necessary for political stability.

In the case of "mixed" economies, the concept of equilibrium must take into consideration the ability of the country to balance its international accounts without the aid of exchange and trade controls outside of the controlled sector, while at the same time financing those imports necessary to achieve its pre-determined goals in the controlled sector. For example, the government might control imports of all industrial raw materials, capital equipment, and basic foodstuffs but in the absence of balance-of-payments difficulties would permit free importation of other categories of commodities.

If in the case of controlled or partially controlled economies short-run equilibrium as we have defined it is consistent with the existence of trade controls, what are the criteria for determining the existence of disequilibrium? Clearly a country is not in equilibrium if its current receipts of foreign exchange, including normal capital imports,⁵ are insufficient to pay for the raw material imports required to maintain its industries at the desired level of production, the imports of essential commodities needed to maintain pre-determined standards of consumption, the imports of capital equipment and materials for planned investments, and for its various commitments on invisible account. It may turn out that balance-of-payments equilibrium in the short run is impossible except at the cost of a disruption of important industries, the shelving of urgent reconstruction projects, or a politically disastrous reduction in living standards. This is indeed the situation among many of the countries included in the European Recovery Program. When a disequilibrium develops, controlled economies must either draw on their reserves, obtain financial assistance from abroad or reduce their imports. Unless there exists a substantial volume of luxury or nonessential imports, a reduction in imports may be quite difficult to achieve in the short run because the economy is geared to a particular level of import requirements. In time, industries can be reorganized, substitutes for imported commodities can be found and standards of consumption can be altered. Equilibrium in controlled economies, however, is eventually restored not so much by the effects of the shift in the balance of payments on incomes and prices, but by a realization of the plans of the economic authorities for the achievement of their investment and consumption goals without further for-

⁵ Normal capital imports exclude emergency loans and grants from other countries and international lending organizations. They would include loans from the World Bank and the Export-Import Bank for planned capital investments.

eign assistance or the liquidation of reserves, or by a revision of their basic economic plans and objectives.

In the case of partially controlled economies, an evidence of disequilibrium would be an extension or tightening up of existing import controls or the failure to achieve desired objectives in the controlled sector. Additional exports might be brought under the licensing system and perhaps an effort made to increase exports by diverting resources from commodities produced for home consumption. Restoration of equilibrium in partially controlled economies can be said to be completed only after temporary restrictions on transactions in the uncontrolled sector have been removed. Thus, if the economic authorities have brought raw materials, investment goods and basic foods and fibers permanently under state control, but normally permit the free importation of consumers' goods, any restriction on the importation of consumers' goods might be considered as a departure from equilibrium, unless similar restrictions or taxes were placed on domestically produced goods of the same general type. The latter would of course represent an extension of the controlled sector of the economy.

To say that disequilibrium exists for controlled economies when plans are not realized may be open to the charge of question begging. However, there is a genuine need for a working concept of equilibrium applicable to controlled economies.⁶ The concept of balance-of-payments equilibrium is employed in the decisions of international financial institutions such as the Monetary Fund and the World Bank, and plays an important role in determining the need for financial assistance under the European Recovery Program and other U. S. government foreign aid programs. It is an important tool in international economic analysis generally and needs to be redefined to conform with current realities. The point to be kept in mind is that disequilibrium has significance only in the context of the organization of the economy under consideration, and of the objectives of its planning authorities. The fact that a country is unable to achieve a balance in its international accounts can no longer be employed as a criterion for the granting of short-term financial assistance in the expectation that the balance will in time be automatically restored. Nor can this fact always be considered as a sufficient justification for exchange depreciation or other remedial actions on the part of the country concerned.

Balance-of-payments deficits may be planned or unplanned under

⁶ See my "Role of the International Monetary Agreements in a World of Planned Economies," *Jour. Pol. Econ.*, Vol. LV, No. 6 (Dec., 1947), pp. 497-512. See also my "Reply" to a criticism of this article, *Jour. Pol. Econ.*, Vol. LVI, No. 5 (Oct., 1948), pp. 446-50. It has been suggested that we need a new term such as "planned international balance" to describe equilibrium for controlled economies.

controlled or partially controlled economic systems. Obviously such deficits will not be planned unless the means of meeting them are available. The deficits of the ERP countries are planned, and the Economic Cooperation Administration has asked the countries receiving United States financial aid to plan their investment, production, and trade so as to enable them to achieve certain consumption goals by 1952 without further United States assistance. Whether or not the realization of these goals, assuming they can be realized, will mean equilibrium for the European Recovery Program countries, depends upon the organization of their economies and their ability to achieve a balance in their international accounts without the use of restrictions which violate the basic principles of their particular economic organization, *e.g.*, import quotas needed for balance-of-payments reasons imposed on types of commodities the consumption of which is normally not controlled.

Controlled and "mixed" economies may also experience unplanned deficits in their balance of payments. Among the causes of unplanned disequilibrium we may cite war and national disasters, crop failures, strikes and political disturbances, domestic inflation, the inability to market exports abroad either because of price factors or shifts in foreign demand, or simply poor planning and forecasting. In the case of "mixed" economies where production and distribution are only partially controlled, planning and forecasting become much more hazardous and consequently equilibrium more difficult to maintain. For the uncontrolled sector of the economy reliance must be largely on indirect controls of a monetary and fiscal nature.

Thus far, we have spoken of disequilibrium in terms of a country's over-all balance. In periods when currencies are almost universally inconvertible a country may be in over-all balance but because of the inability to convert current surpluses with some countries into the currencies of other countries, that country may find it necessary to direct its trade by discriminatory measures. Such measures would include discriminatory import regulations against the country whose currency was in short supply and perhaps measures designed to increase exports to that area. Although this is a clear case of disequilibrium for the country concerned, the country may be the victim of a worldwide disequilibrium. In such cases the remedy may lie beyond the power of the individual country acting unilaterally, except at the cost of far-reaching changes in the pattern of its international trade.

Sources of Postwar Disequilibrium

In discussing the sources of postwar disequilibrium, it is important first of all to make clear just what kind of disequilibrium we are talk-

ing about. The vast majority of the countries have what we have called "mixed" economies with varying degrees of governmental control. The long-run objective of most of these countries is to achieve a large measure of consumer choice with respect to home-produced and imported commodities alike, and also to restore to private enterprise a large measure of freedom as to what to produce and where to sell, and where to buy raw materials and capital equipment. Unless these countries can count on foreign assistance for an indefinite period of time, they must either achieve equilibrium in the sense in which we have used it in the preceding section, or they must abandon certain of their economic objectives. The alternatives may be the abandonment of certain investment or social welfare objectives, or the objectives of restoring freedom of consumers' choice and freedom for business enterprise in certain fields. The failure of a "mixed" economy to restore freedom of consumers' choice and freedom of business enterprise in those sectors of the economy for which such freedom is required in accordance with the basic structure and objectives of the country concerned will be considered as an evidence of disequilibrium for that country. One of the reasons for such failure may be the fact that the restoration of economic freedom is found to be incompatible with other economic objectives considered to have a higher priority. Disequilibrium for a "mixed" economy would also be evidenced by an inability to purchase with current foreign-exchange receipts sufficient imports to achieve a reasonable level of productive efficiency and standard of consumption, consistent with its productive resources. This would also be an evidence of disequilibrium for more or less completely controlled economies. In the following paragraphs we will discuss the sources of postwar disequilibrium in the special sense in which we have just defined it.

The major source of disequilibrium in the immediate postwar period has been the destruction and general dislocation caused by the war itself. Given a few years of peace and adequate Western Hemisphere assistance to rebuild and restock the major economies of the world so as to permit a return to something like prewar per capita production levels, the disequilibrium resulting from the physical destruction and temporary disruption of production and commerce caused by the war can be eliminated. What we are concerned with here are possible sources of disequilibrium which may persist perhaps for the next generation or more, after production has been restored to a level approximating the potentialities of the human and material resources of the countries of the world. For purposes of analysis I have classified these sources of disequilibrium in four categories: (1) relative changes in levels of real national income; (2) domestic economic instability; (3) changes

in international creditor-debtor relationships; and (4) shifts in the structure of world production and in the character of world demand. Both (3) and (4) may give rise to what was called "structural disequilibrium" in the opening paragraphs of this article. However the changes in the "income from investment" account in the balance of payments of most trading countries have been so significant as to warrant separate treatment. These four categories are by no means water-tight and it will be readily seen that developments in any one of them will affect the other three.

1. *Relative Changes in Incomes*

Of the four general sources of disequilibrium outlined above, probably the greatest emphasis in recent years has been placed on relative shifts in national incomes as the leading cause of disequilibrium.⁷ This concern is largely based upon the fear of another major depression in the United States. While I quite agree that relative shifts in the levels of national income may be an important factor contributing to disequilibrium in the postwar years, it is by no means certain that economic conditions of the early 1930's will be repeated. In fact, there is reason to believe that national governments are not likely to permit prolonged and severe depressions in the future. Not only have the governments of nearly all major countries, including that of the United States, accepted as a matter of national policy the responsibility for maintaining high levels of employment, but the increased functions of government have brought a substantially larger proportion of the national income under the control of governmental authorities.

Although we may not again see depressions of the 1929-1933 proportions, shifts in the relative levels of income may still be an important source of international disequilibrium. Short-term cyclical movements in incomes and employment and perhaps extended periods of moderately high unemployment are of course quite probable in the United States and other countries where economies are largely uncontrolled. Although controlled economies will also be subject to fluctuations in real income and employment with changes in the structure of production, governmental authorities are better able to maintain total monetary demand. Hence, money income, if not real income, is less likely to decline in the controlled economies than in the relatively free economies.

If we are to separate relative changes in national income from other causal factors, we must consider only changes in real income. In spite

⁷ See, for example, T. Balogh, "The International Aspects of Full Employment," *The Economics of Full Employment* (Oxford Institute of Statistics, 1944).

of the fact that, barring depressions, real income in the United States may continue to increase at a rate of 3 to 4 per cent per year, it is quite possible that real incomes in many undeveloped areas of the world will rise more rapidly than in the United States. The industrialization programs of Latin America and Asiatic countries, and perhaps a more efficient utilization of human and material resources in previously undeveloped or primitive areas may well make for a rapid expansion in real incomes the world over. Thus disequilibria from shifts in relative incomes in different countries may come not so much from depressions in the United States as from continually rising incomes abroad. The propensity to import in most countries of the world is undoubtedly higher under present conditions than in the United States where a diversified economy supplies most of the things for which consumers have a high income elasticity of demand.⁸ Given a higher propensity to import abroad than in the United States, disequilibrium could accompany an increase in incomes in the rest of the world at the same rate at which United States national income increases. But this situation may only be true in the short run. The potential demand for foreign goods of a luxury or semi-luxury type requiring a high proportion of labor may turn out to be quite large if foreign sellers were to market and advertise on a nation-wide scale.

2. *Domestic Instability*

The Western World has lived so long in fear of unemployment and deflation that the possibility of a generation of more or less continual inflationary pressures has not been given very serious consideration. Yet if economies in which investment decisions are made by private enterprise tend toward underinvestment, economies in which investment is largely in the hands of the state may suffer from the opposite condition. Moreover, once the economic authorities have adopted a policy of maintaining full employment and have equipped themselves with the necessary monetary and fiscal instruments for carrying out this objective, errors in planning and forecasting are likely to be made only in the direction which involves the less serious political consequences.

Almost every country, from the most backward agricultural countries to the more advanced industrial ones, has reconstruction and development plans requiring large amounts of capital and foreign ma-

⁸ Dr. T. C. Chang in an article entitled "International Comparison of Demand for Imports" has calculated the income elasticity of demand for imports for a number of countries. In the case of highly industrialized countries like the United States and the United Kingdom, income elasticity is shown to be substantially lower than income elasticities in less industrialized and agricultural countries. *Review of Economic Studies*, Vol. XIII (2), No. 34 (1945-46), pp. 53-67.

terials and equipment.⁹ This development is likely to affect the demand for United States products in two important ways. First, the demand for United States capital equipment may be maintained at a relatively high level for the next generation or so, since barring another world war, only the United States may have the surplus productive capacity to meet world needs for a large number of capital items. Regardless of competitive price adjustments there would be only one country capable of meeting the demand. A second way in which the potential demand for United States commodities may be sustained at a high level is through the increased purchasing power of the masses in the countries undergoing rapid capital development. In many countries industrialization will undoubtedly be accompanied by a redistribution of income in favor of the working classes at the expense of landed aristocracy or other property owners. Such redistribution will mean a reduction in the propensity to save and an increase in the propensity to import. At the same time, the development projects will be absorbing a large share of the foreign exchange receipts and may in some cases reduce the proportion of material and human resources available for the production of exports.

In order for large-scale capital projects calling for an accelerated rate of capital accumulation to be financed from internal sources without inflation, it is necessary either to have unemployed human and material resources or to put into operation a rigorous system of fiscal, monetary,¹⁰ wage, and credit controls which will restrict purchasing power to the amount of available consumers' goods. External financing through loans or grants for developmental purposes are likely to be limited to the foreign exchange required to purchase the materials and equipment directly employed in the project itself and which are not available from internal sources.¹¹ Ordinarily one-half to two-thirds of the expenditures on capital projects are made for local materials and services. In few countries outside of the United States is there a large volume of volutary saving available for domestic investment, and rapid capital accumulation can only be realized at the expense of living standards which are already low relative to prewar standards. Moreover, few governments have the courage to take the necessary steps to curtail

⁹ See *Economic Report: Salient Features of the World Economic Situation, 1945-1947*, United Nations, Department of Economic Affairs (Lake Success, Jan., 1948), pp. 243-55, for a summary of investment projects in various countries.

¹⁰ Some economists believe that a substantial increase in the volume of savings can be induced by raising interest rates, although in the opinion of the author there are severe limitations on purely monetary measures.

¹¹ For example, neither the World Bank nor the U. S. Export-Import Bank will ordinarily make loans to finance local currency expenditures in the borrowing country.

the purchasing power of the masses as a means of reducing real consumption. The propensity to save has been generally reduced by mounting taxes on the wealthy and most countries are seeking to raise the real incomes of the masses by an extension of social services. The net result is that capital accumulation in many foreign countries is being financed in large measure through inflation.¹²

For many countries, the need for rapid capital investment in order to achieve the structural changes necessary to realize international equilibrium within a relatively short period presents a real dilemma. If monetary incomes are restricted to the point where consumer demand just equals the current output of consumers' goods, the expansion of production in certain fields may be accompanied by a disruption of other industries. Inflexible wage policies on the part of labor unions plus the necessity of attracting labor and resources to the investment industries may render extremely difficult the realization of production goals in the face of disinflationary policies. Disinflationary measures may also be hampered by the existence of sizeable accumulations of liquid assets in the hands of the public which could be used to defeat attempts to lower consumption standards on the part of the holders. It is quite likely, therefore, that many countries will find it impossible (for political and economic reasons) to carry out large investment programs and avoid a certain degree of domestic inflation at the same time.

How long will disequilibrium from these sources continue? Essentially what we are confronted with are the international repercussions of a worldwide trend toward the socialization of investment, *i.e.*, the transfer of investment decisions from private to governmental or quasi-governmental authorities. We are also confronted with the international repercussions of a redistribution of income in favor of the masses and a general weakening of the influence of the international pricing mechanism in economic decisions over production and consumption. In time, patterns of economic controls may be evolved which will restore domestic stability and international equilibrium. The new capital instruments may raise real per capita income (unless defeated by population pressure) and economic authorities may adopt appropriate controls which will relate money incomes and voluntary saving to the level of capital expenditures. Finally, imports for investment purposes will have to be planned in relation to the over-all demand for imports in such a way as to avoid either a balance-of-payments deficit or an in-

¹² The ratio of gross domestic investment to gross national product is substantially higher than prewar in the case of many European countries. For example, in the case of the United Kingdom the ratio was 20.4 per cent in 1947 as compared with 14.5 per cent in 1938. (Source of data: *National Income and Expenditure of the U. K., 1947* [Md. 7371]) A similar increase in this ratio appears to have taken place in France and the Netherlands.

crease in the scope of direct consumer controls not contemplated by the basic plan for the economy.¹³

3. *Changes in Creditor-Debtor Relations*

A source of postwar disequilibrium which especially affects the United Kingdom and certain countries of Continental Europe is the loss of prewar sources of invisible income. In 1938, net invisible income for Europe as a whole from non-European sources amounted to about \$2.1 billion, an amount which equaled Europe's deficit on trade account.¹⁴ In 1947, Europe had a net deficit on invisible account of \$0.6 billion, \$0.4 billion of which was with the United States. A part of this deterioration in Europe's invisible account is due to a temporary reduction in tourist trade and shipping services, and we may look forward to a rapid restoration of these sources of income. The large overseas expenditures for maintaining troops and fighting colonial wars, and for relief in occupied areas may also be regarded as temporary. However, approximately a billion dollars of the reduction in Europe's net invisible income is accounted for by a net reduction in income from foreign investment, about half of which can be attributed to the United Kingdom alone.

Although income from investments in certain of the war-devastated areas may be eventually restored, the over-all position of Europe on investment account is certain to deteriorate with the making of interest payments on the large dollar loans. From July 1, 1945 through June 30, 1948, loans and credits to foreign countries by the United States government totaled nearly \$12 billion and an additional \$1.2 billion was loaned or committed by the World Bank and the Monetary Fund. If we add to these amounts long-term private investments abroad since the war, we reach a figure of over \$15 billion on which service in dollars must be made, the vast bulk of which must come from the countries of Western Europe. Over the next three years, assuming that the Economic Cooperation Administration program is continued, total foreign investment on both private and governmental account is likely to increase by another three to four billion dollars, with perhaps an additional \$2 or \$3 billion in loans from the World Fund and Bank. The net effect of these loans upon the international balance of payments will of course depend upon whether or not new loans will continue to be made in amounts sufficient to offset repayments. Private foreign investments probably cannot be counted on to maintain the necessary gross level of investment so that the outcome becomes largely a matter

¹³ For example, if consumers are to be denied certain luxuries they should be denied both foreign and domestically produced luxuries of the same category.

¹⁴ See *A Survey of the Economic Situation and Prospects of Europe*, p. 55.

of United States governmental lending policy. But interest payments alone on over \$20 billion in additional foreign indebtedness will absorb a significant portion of the dollar income of the rest of the world.¹⁵

4. *Structural Changes*

Probably the most serious obstacle to the restoration of a balanced world economy which would permit countries, planned and unplanned, to achieve the maximum efficiency in the use of their productive resources and the highest living standards for their people lies in deep-seated maladjustments in the structure of world production and demand. Some of these structural factors are a direct outgrowth of the late war, while others are perhaps a product of far-reaching socio-political and technological development which are taking place too rapidly to be accommodated by the international economic organism. We will summarize some of these structural factors in the following paragraphs.

Although the overwhelming demand for United States commodities during the immediate postwar period can be explained by the disruption of production outside the Western Hemisphere caused by the war, the capital needs for reconstruction and the backlog of deferred demand built up during the period of wartime shortages, there is considerable evidence that the potential demand for United States commodities in excess of the dollars supplied by United States imports may continue for many years after prewar production levels have been generally restored or even substantially exceeded. Mention has already been made of large-scale industrialization and development programs throughout the world which call for large amounts of specialized capital and materials available in surplus quantities only in the Western Hemisphere. This enlarged demand for investment type commodities may be superimposed upon the normal heavy dependence upon United States and Western Hemisphere exports, unless offset by compensating shifts in demand for the exports of other areas. Such shifts, however, do not depend simply upon competitive price relationships but are in

¹⁵ According to the Department of Commerce publication, *International Transactions of the U. S. During the War*, by 1951 receipts of interest and amortization on all U. S. government postwar loans should amount to about \$450 million, and if dollar loans through the International Bank should rise to \$4 billion, an additional \$200 million in interest and amortization will be required. Together with payments of around \$1 billion on loans and investments existing at the end of the war, total payments will amount to \$1.6 or \$1.7 billion before allowance is made for additional governmental and private loans and investments in the years following 1947 (p. 161). During 1947 and 1948 net private long-term capital flow has been averaging around \$700 million per year, and over \$1 billion in loans were extended by the United States during 1948. It seems quite likely therefore that earnings and amortization payments owed to the United States will be well over \$2 billion by 1951.

considerable measure dependent upon the creation of new sources of supply in areas outside the Western Hemisphere.

What is the result of a shift in world demand in favor of the products of a particular country or area? Let us assume that before the shift occurs all countries have succeeded in achieving a balance in their current international accounts. Immediately after the shift certain countries will find themselves with current account deficits which they must correct by reducing their imports or by adopting measures to expand their exports either to the country or area whose exports have increased, say the United States, or to third countries. Now let us assume for the moment that the demand for imports on the part of the United States is inelastic, and that the elasticity of substitution between United States exports and the exports of the rest of the world is quite low. Under these assumptions, equilibrium must be restored either by an expansion of production in the rest of the world of the commodities which constitute the exports of the United States or by a reduction in the demand for these commodities. But it may not be possible to realize either of these alternatives without substantial adjustments in the structure of world production.

The immediate effect of a shift in world demand in favor of a country like the United States may be a world shortage of dollars and the consequent inability of some countries which normally have deficits within the dollar area to discharge these deficits by converting surpluses with other areas into dollars. Canada and Belgium are examples of countries whose balance of payments difficulties in the postwar are in large measure traceable to this factor. Europe as a whole normally has a deficit with the United States which is settled by dollars earned largely from the Far East. It is quite possible that countries such as India, Indonesia and Malaya will no longer be important sources of net dollars for Europe in the future. The greater political independence of these countries has been accompanied by a desire for rapid industrialization and the inauguration of large-scale development projects. There is considerable evidence that these countries will use their dollar earnings for purchases in the United States rather than transfer them to Europe as was the case before the war.¹⁶

¹⁶ The prospects of Europe's being able to settle its deficit with the United States by means of a surplus with non-European countries other than the United States is discussed in the United Nations' Report entitled "A Survey of the Economic Situation and Prospects of Europe," p. 69 ff. This Report concludes as follows: "The huge disequilibriums manifested in their (non-European countries) trade with the United States in 1947 is bound to diminish sooner or later. But the demand for imports from the United States, while not capable of being fully satisfied, may well continue to press hard against the available supply of dollar exchange and to leave little over for trade settlements with Europe" (p. 70).

Another structural factor which may contribute to a possible chronic disequilibrium in the postwar period is the heavy dependence of Western Europe on the Western Hemisphere for agricultural products.¹⁷ This dependence has increased with the decline in grain imports from Eastern into Western Europe. To the extent that this decline is the result of physical factors, *i.e.*, shortages of farm equipment, etc., it may be temporary. But there is evidence that political factors may also be responsible for the reduction in exportable surpluses of agricultural commodities by the Russian dominated economies.¹⁸

While the rest of the world has become increasingly dependent upon United States agricultural products, the technical superiority of United States industrial production makes it difficult for other industrial countries to compete with our manufactured products both in United States and foreign markets. An abundance of capital and superior production techniques, coupled with a large internal market provides an enormous advantage in most fields of industrial production. While it is true that trade takes place in response to differences in comparative costs rather than absolute costs, a country which is continually introducing new techniques which lower costs and is able to introduce new products which capture the fancy of the rest of the world may be able to maintain a more or less permanent competitive advantage. This does not mean that equilibrium could not be restored, but the required adjustments may not be made rapidly enough to compensate for continual changes in the structure of world demand and supply. Finally, mention should be made of the tendency on the part of the United States to make itself independent of raw material imports from outside the Western Hemisphere. The tin smelter on the Texas seaboard and the synthetic rubber plants are evidences of this development. Economic independence in a growing number of fields has become a matter of governmental policy for reasons of national defense. Offsetting these autarchic tendencies is the fact that the United States is rapidly reducing its reserves of some important natural resources, *e.g.*, petroleum, copper, iron ore, lead and zinc.

Means of Correcting International Disequilibrium

In discussing measures for correcting balance-of-payments disequilibrium, we must distinguish between actions undertaken by countries

¹⁷ By 1951, Europe's bread grain production is expected to reach 96 per cent of the prewar level. But to achieve prewar consumption Europe will, according to estimates by the Food and Agriculture Organization, need to import 15.5 million tons of bread grain, annually, or 6 million tons more than prewar. Of this, some 6 to 8 million tons will have to come from the United States. (See *New York Times*, September 3, 1948).

¹⁸ See for example, "Food from Eastern Europe," *The Economist*, for July 17 and July 24, 1948.

unilaterally and those adjustments which need to be taken by several countries in concert. Certain of the deep-seated maladjustments in the world today are not likely to be resolved by unilateral action alone. This is particularly true of structural maladjustments such as those which characterize the postwar European economies. It is for this reason that the ECA is insisting on a cooperative self-help program for the European Recovery Program countries rather than the granting of United States aid on a country-by-country basis. There are, in general, four types of measures which may be taken for the correction of disequilibrium: (1) monetary, fiscal and other economic measures designed to achieve internal economic stability; (2) exchange rate adjustments; (3) bilateral or multilateral trading arrangements; and (4) adjustments in the structure of production.

1. Measures for Internal Stability

There can be little doubt that the achievement of internal stability is frequently necessary for the correction of balance-of-payments difficulties on the part of planned, "mixed," and unplanned economies alike. The general level of purchasing power must be related to the volume of consumers' goods, both home-produced and imported, which is made available. In the case of completely controlled economies where the volume of consumers' goods, both imported and home-produced, is directly controlled, an excess of disposable income in the hands of consumers would not directly affect the trade balance. Price inflation and the diversion of rationed commodities to black markets might, however, result in a maldistribution of real income which would seriously impair the living standards and productive capacity of a portion of the population. This result would be an evidence of disequilibrium according to the criteria which we have established above. In mixed and uncontrolled economies, where home investment and foreign trade are partly or wholly determined by private decisions, monetary and fiscal measures will need to be largely relied upon for limiting purchasing power, for encouraging exports, and for determining the volume of savings, investment, and the general level of imports. This does not mean that direct controls can always be dispensed with by uncontrolled economies. Sudden shifts in the trade balance require time to correct by fiscal and monetary measures. Moreover, it may not be possible to reduce total monetary demand sufficiently in the short run to achieve an international balance, without causing great economic hardship and unemployment.

It is frequently said that all a country needs to do to restore international equilibrium is to adopt appropriate monetary and fiscal controls. If by this statement it is meant that a country can apply defla-

tionary measures to the point where its international account is balanced without the aid of external trade controls, no one can dispute it. However, unless certain structural changes take place in the economy, the results of drastic deflationary action may very well be disastrous for production and living standards. Deflationary measures may be prevented from shifting resources to the export industries by price rigidities, or a lack of mobility of labor and other factors of production. Moreover, it may prove impossible for a country to undertake a large investment program under conditions of full employment without at least a certain degree of inflation. This is particularly true where trade unions are able to prevent any downward adjustment of wages and continually press for an increase in existing wage scales.

2. *Exchange Rate Adjustments*¹⁹

Although a country may not be able to reduce its monetary income and prices by deflation, it can always reduce them in terms of foreign currencies by devaluation.²⁰ The effect of exchange devaluation on a country's balance of payments will depend upon a number of complex economic and institutional factors including (a) the system of economic controls in the economy; (b) the demand and supply elasticities of the commodities and services entering into the balance of payments of the country in question; (c) the capacity of the country to make the adjustments in the structure of its productive facilities in response to alterations in external and internal cost-price relationships; and (d) the repercussions of devaluation upon the trade and exchange policies of other countries.

a. *The system of economic controls.* In an economy in which all imports are rigidly controlled and exportable surpluses determined by allocation, the chief function of the exchange rate may be that of influencing the demand for exports. (It may not even have this function in a state controlled economy which prices its exports independently of domestic costs.) In economies in which export demand is permitted to compete with domestic demand, the rate will influence the volume of commodities directed to the export market. This fact is frequently overlooked by those who claim that devaluation cannot improve the balance of payments because the country in question is having no

¹⁹ For excellent discussions of the effects of exchange rate adjustments upon the balance of payments see Howard S. Ellis, "The Dollar Shortage in Theory and Fact," *Canadian Jour. Econ. and Pol. Sci.*, Vol. 14, No. 3 (Aug., 1948) pp. 301-11; and Lloyd A. Metzler, "The Theory of International Trade," in *A Survey of Contemporary Economics*, edited by Howard S. Ellis, (Blakiston, 1948), pp. 210-54.

²⁰ This is true only in the short run. Over a longer period, the initial reduction in prices in terms of foreign currencies may be offset by an increase in domestic prices brought about by the devaluation, or by competitive depreciation on the part of other countries.

difficulty in selling its exportable surpluses. The latter argument is intelligible only if it is assumed that a further diversion of resources to the export industries will reduce consumption standards to an intolerable level or prevent the making of capital investments which are necessary for the eventual restoration of equilibrium.

Where imports are rigidly controlled, devaluation will not reduce imports unless import prices rise sufficiently to reduce demand below existing import quotas. Also where only unessential imports are limited by direct controls, devaluation may fail to reduce imports if the demand for essential imports is quite inelastic. The rise in the domestic prices of imports may, however, be significant for the restoration of the balance of payments, since consumer demand may be diverted from the products of home industry, thereby releasing additional resources for the export industries. Whether or not devaluation is inflationary depends upon the wage policy, the fiscal and monetary policies, and the amount of latent inflation already present in the economy. Thus the argument that for a country which controls its imports by direct means and has no difficulty in selling its exports devaluation is merely inflationary and will not improve the trade balance, needs to be re-examined.

b. *Demand and supply elasticities.* Recent statistical estimates of the demand for imports in various countries have revealed remarkably low price elasticities.²¹ It has also been shown that the elasticity of world demand for the total exports of most countries is substantially less than unity.²² Great care must be exercised in drawing conclusions from these statistically derived estimates of import demand elasticities as regards the effects of exchange rate adjustments on the trade balance. Although in the short run at least, the demand for a nation's

²¹ See T. C. Chang, "International Comparison of Demand for Imports," *Rev. Econ. Studies*, Vol. XIII (2), No. 34, pp. 53-67. In this article Dr. Chang estimates the price elasticities of import demand for the United Kingdom and the United States for the interwar period to be -0.28 and -0.97 respectively; see also Randall Hinshaw, "American Prosperity and the British Balance of Payments Problem," *Rev. of Econ. Stat.*, Feb., 1945.

²² See, for example, T. C. Chang, "A Statistical Note on World Demand for Exports," *Rev. of Econ. and Stat.*, Vol. XXX, No. 2 (May, 1948), pp. 106-16. Dr. Chang shows that for the interwar period the sum of the elasticities of home and foreign demand was for most countries close to unity. In a few countries this critical value was above unity but for the United Kingdom, for example, it was -0.68 . In an unpublished paper Dr. Randall Hinshaw points out that since most statistically derived estimates of the elasticity of demand assume a constant level of real income, *i.e.*, the level of income is held constant by means of partial correlation, the effects of the fall in real income in a depreciating country are ignored. The fall in real income resulting from the rise in domestic prices of internationally traded commodities will tend to shift the demand curve for imports to the left. Thus it is quite possible for a country's over-all demand for imports, at a given level of real income, to be inelastic with respect to price and, at the same time, for depreciation to be accompanied by a reduction in the domestic (as well as the foreign currency) value of imports.

imports may be largely determined by the structure of its production and trade and by its national income, changes in exchange rates are capable of bringing about shifts in the demand for imports and in the supply of exports through changes in real income and other changes which may not be accounted for by estimates of demand elasticities derived from cyclical data.

The existence of short-run inelasticities of demand for *total* imports and for the world demand for the *total* exports of individual countries is by no means conclusive evidence that exchange depreciation cannot improve a country's balance of payments. In the first place the demand for a portion of a country's imports and certain of its commodity exports will undoubtedly prove to be elastic. Even if we assume that the total demand for imports is inelastic, total expenditures for imports in terms of *foreign* currencies must decline with devaluation so long as there is any reduction in the physical quantities imported.²³ If the supply of imports is less than perfectly elastic, there will be a further saving of foreign exchange.

Turning to the demand for the exports of a country, even though total world demand is inelastic, the demand for a portion of its exports will undoubtedly prove to be elastic. The net effect of devaluation will depend upon what happens to the prices of its exports in terms of foreign currencies, *i.e.*, the elasticity of supply of the devaluing country's exports. If devaluation enables the country to reduce the foreign currency prices of those commodities for which the demand is elastic while maintaining the foreign currency prices of those commodities for which the foreign demand is inelastic, its balance-of-payments position will be improved.

It is clear that, in considering the effects of devaluation on a country's balance of payments, we must be concerned not only with demand elasticities for imports and exports but also with supply elasticities and pricing policies.²⁴ If the supply of those exports for which the demand is inelastic is also inelastic (or if prices in terms of foreign currencies are maintained by private cartels or government control) and if both the supply and the demand for the remaining exports are elastic, devaluation will increase total foreign-exchange receipts from exports. Moreover, it is not necessary to assume that devaluation will reduce a country's terms of trade for all or even the bulk of its trade.

²³ Total expenditures on imports in terms of foreign currencies will decrease with a fall in the exchange rate as long as the elasticity of total demand for imports is greater than zero.

²⁴ See Joan Robinson, "The Foreign Exchanges," in *Essays in the Theory of Employment*, 2nd ed. (Oxford, 1947), p. 142, n. 1. Mrs. Robinson points out that an improvement in the balance may be achieved by devaluation even where the sum of the elasticities of the demand for exports and the demand for imports is less than unity, provided the supply elasticities for imports and exports are sufficiently small.

c. *The ability to make structural adjustments.* A third important consideration in determining the effects of devaluation concerns the relationship between devaluation and the structure of the economy. A change in internal and external price-cost relationships may be a necessary but not sufficient cause for the restoration of a country's balance of payments. A lack of capital, price and wage rigidities, inadequate incentives for enterprise, or plain inertia may be responsible for the failure of production to respond to changes in cost-price relationship resulting for the alteration of exchange rates. These structural factors are discussed below.

d. *Repercussions of devaluation on other countries.* Exchange rate adjustments as a means of dealing with worldwide equilibrium are limited by the fact that the demand for one country's exports may be elastic only under the assumption that its competitors maintain their exchange rates and export prices. Hence in order not to invite competitive depreciation, which in the case of an inelastic foreign demand would prove to be self-defeating, exchange rate adjustments should not be made on a unilateral and piecemeal basis. The practice of unilateral adjustments may also lead to the use of rates which discriminate as between currencies. Thus, it may be to the advantage of a country to reduce the value of its currency in terms of the currencies of certain countries, e.g., the dollar area, while maintaining its rate *vis-à-vis* other countries. For example, a European country may want to encourage a diversion of its exports from other European countries with inflated currencies to the United States. This situation is undoubtedly responsible for the use of discriminatory rates by Italy and France in 1948.

3. *Discriminatory Arrangements*

When countries are unable to balance their international accounts on a multilateral basis, they may be able to do so on a discriminatory basis. Whether or not a country is able to achieve equilibrium through discrimination depends upon whether it can find an outlet for its exports which will enable it to meet its import requirements. If, for example, the only available source of certain raw materials and capital equipment which a country needs is the United States, bilateral deals with third countries will not secure these materials. Discriminatory arrangements may, however, reduce that country's dollar requirements for other commodities available elsewhere and provide a market for the exports to be traded against them. Where import and export controls are not employed, discrimination may be achieved by the use of discriminatory exchange rates, but similar commodities must be available in the areas from which imports are to be increased, i.e., the elasticity of substitution must be fairly high.

Strictly bilateral arrangements, although better than going without needed imports, have well-known limitations. The larger the area of multilateral trading, the more efficient trade becomes. It may be desirable, therefore, for a group of countries to engage in multilateral trade among themselves while discriminating against other areas.²⁵ However, potential demand on the part of a group of countries joined together in a multilateral payments system for the exports of another currency area may still be greater than foreign exchange receipts from current transactions. Thus, although the new intra-European clearing arrangement²⁶ may help to reduce the dependence of the Economic Recovery Program countries for Western Hemisphere commodities by promoting a freer exchange of European commodities, these countries will still need outside assistance for meeting their deficits with other areas.

Do discriminatory arrangements provide a permanent solution to the problem of worldwide disequilibrium? Although an adequate answer to this question would require another article or perhaps a volume, it is my view that such devices should be considered as short-term expedients only. Bilateral or regional multilateral arrangements may meet an immediate need for the restoration of trade which has been hampered by a shortage of generally acceptable means of payment. Regional multilateral payments arrangements may also help to restore equilibrium by providing a large protected market for new industries, the rapid development of which is necessary in order to reduce the dependence of members of the region on other areas with which the region as a whole may be out of balance. But after the structural adjustments have been made and exchange rates established at appropriate levels, these industries should be able to stand on their own feet in competition with those of other regions. Regional multilateral arrangements should eventually be merged with a worldwide multilateral system, although it might be desirable to retain the regional payments structure so that temporary discrimination against the outside world could be instituted in periods of emergency.

4. *Structural Adjustments*

By structural adjustments we mean adjustments in the structure of production and patterns of consumption which are not brought about by one of the three types of measures discussed in the preceding para-

²⁵ I have discussed this subject in an article entitled "Regional Multilateral Payments Arrangements," *Quart. Jour. Econ.*, Vol. LXII, No. 4 (Aug., 1948), pp. 500-18.; See also Robert W. Bean, "European Multilateral Clearing," *Jour. Pol. Econ.*, Vol. LVI, No. 5 (Oct., 1948), pp. 403-15.

²⁶ For a discussion of the intra-European payments plan see *Second Report to Congress of the Economic Cooperation Administration*, 1949, pp. 11-15.

graphs. In some cases, the adjustments required for the restoration of equilibrium could be brought about by appropriate internal monetary and fiscal means, but for one reason or another governments may choose not to employ them. In other cases, restoration of equilibrium without severe disruption of the economy may not be possible except by direct or indirect action on the part of the economic authorities to alter the structure of the economy. In other words, internal financial measures, exchange rate adjustments or special trade and payments arrangements may not be sufficient or may not act quickly enough to restore an international balance.

In controlled economies, restoration of equilibrium may require the establishment of new industries, the expansion of old ones or an increase in agriculture output for home consumption or export. It may also mean the contraction or elimination of certain industries. On the consumption side, restoration of equilibrium may require the elimination of certain luxury items such as private automobiles, or a cheapening of housing accommodations to be made available to the public.

In relatively free economies, changes in the structure of production may be achieved by special encouragement to certain industries in the form of low interest loans, free technical assistance or tax concessions. Other industries may be discouraged by discriminatory taxation and other measures which do not require a direct control of industries by the government. Although the government may be able to discourage certain industries by indirect means, it may be impossible to expand other industries except by direct encouragement or promotion. There may be cases where the necessary risk capital is not forthcoming without direct government intervention or where the necessary capital can only be obtained from abroad. The fact that in recent years international loans have been made largely on an intergovernmental basis, has tended to increase governmental responsibility and control in borrowing countries.

The question arises as to why, in the case of relatively free economies, necessary structural changes for the restoration of equilibrium cannot be brought about by internal monetary and fiscal measures and appropriate changes in the exchange rate. The answer is that in some cases equilibrium could be restored without governmental action to affect structural changes but only at the cost of unemployment or drastically reduced living standards. The economic organism of a modern industrial nation simply does not have the flexibility and sensitivity to changes in the pricing mechanism attributed to it by classical international trade theory. The expansion of certain industries and the contraction in others which may be dictated by rapid changes in the balance-of-payments position of a country may not take place with

sufficient speed through the operation of competitive forces in free economies. It requires considerable time to attract private risk capital to new industries especially when adequate incentives for venture capital are lacking. Price and wage rigidities interfere with the transfer of resources from established industries. Moreover, new export industries and industries supplying home needs formerly met by imports often require large amounts of foreign equipment so that the initial result of the structural adjustment may be an increased demand for imports. It may be necessary, therefore, for the government to obtain the necessary financing from abroad. If an attempt were made to force the required structural adjustments solely by means of deflationary financial measures, the result might be immediate unemployment, the disruption of industry and perhaps a permanent lowering of living standards.

The postwar situation in Europe is an example of the need for far-reaching structural adjustments for the restoration of balance-of-payments equilibrium which could not be brought about by internal financial measures alone except at the cost of reducing the living standards of a large part of the population to starvation levels. According to the report of the Economic Commission for Europe,²⁷ if Europe is to achieve equilibrium in her balance of payments and to res... standards of living it will be necessary to close a balance-of-payments gap of \$3.3 billion in terms of 1947 prices. This gap remains in spite of the fact that by the end of 1948 prewar industrial production in most Western European countries had already been exceeded. This deterioration in Europe's balance of payments was in considerable measure a result of the reduction in net investment income and changes in other invisible items. In the case of the United Kingdom, whose total production and volume of exports exceeds prewar levels by a substantial margin, practically all of her balance-of-payments difficulties can be traced to the deterioration of the invisible account.

The expansion in European heavy industry and the other changes in the pattern of production which are necessary for Europe to achieve equilibrium by the end of the four-year recovery period not only require large amounts of foreign capital but also a considerable degree of national and international planning and cooperation. It is unlikely that the steps necessary for the restoration of equilibrium at high levels of production can be brought about solely by exchange-rate adjustments and fiscal and monetary measures within the space of a few years. But, to be successful, structural adjustments must be accompanied by appropriate financial measures and exchange-rate adjustments. They may also require trade and payments arrangements with

²⁷ "A Survey of the Economic Situation and Prospects of Europe," pp. 76-77.

other countries. For example, in order for the Economic Recovery Program countries to balance their accounts with the Western Hemisphere, they may need to plan their industries in a complementary fashion and promote intra-European trade by a regional multilateral payments arrangement. Such arrangements will for a time at least involve discrimination against the United States. Eventually, however, after the necessary structural adjustments have taken place, these countries may be able to return to multilateral trade on a worldwide basis.

The United States and World Disequilibrium

Before concluding, it may be appropriate to inquire as to the need for structural adjustments on the part of countries with chronic surpluses, *e.g.*, the United States. If the elasticity of demand for United States imports proves in fact to be less than unity, changes in the relative value of the dollar, and reductions in United States tariffs, may not bring about a substantial increase in United States imports. It might be argued that the entire burden of structural adjustments to achieve equilibrium rests with the rest of the world which is experiencing a dollar shortage. On the other hand, many Europeans and some Americans maintain that if we want to have a world in which nondiscriminatory trade and convertible currencies are possible, the problem of the dollar shortage is in part, at least, an American problem.²⁸ Any attempt to determine whether or not a dollar shortage will continue for an indefinite period in the future would involve the making of long-range estimates of an exceedingly hazardous character. But without predicting our long-run balance-of-payments position we might suggest possible ways in which a reduction in our actual or potential balance-of-payments surplus might be achieved.

If economic and political conditions in the world generally were favorable, the most desirable way of dealing with the dollar problem would be to export large amounts of capital each year, preferably on private account. Special encouragement could be given to such investment by government guarantee of the transferability of earnings into dollars or by other forms of insurance and guarantees. Although foreign investment would increase United States receipts on invisible account, several decades of large outpourings of American capital and technical knowledge would most certainly alter our relative position as a supplier of the world's industrial commodities. Moreover, with the exhaustion of our natural resources, our imports of raw materials will tend to increase.

In the absence of an environment favorable to large-scale United

²⁸ See "Dollars—An American Problem" and "Dollar Shortage Forever," *The Economist*, July 3, 1948 and June 26, 1948 respectively.

States foreign investment, the government might seek to reduce our export surplus by reducing the amount of agricultural products available for export through our agricultural support price and acreage allotment program. We might also place export controls on strategic raw materials or commodities produced from strategic raw materials as a conservation measure. The difficulty with these measures to curtail exports, however, is that we would be doing the world a distinct disservice if alternative sources of supply of these commodities did not exist. Preventing other countries from satisfying their needs for United States commodities is not a realistic solution to the dollar problem.

Measures designed to increase United States imports would be preferable from the standpoint of the world economy. But here we run into the difficulty that the bulk of United States imports takes the form of foodstuffs and crude materials the demand for which is quite inelastic. A large-scale stockpiling program and a conservation program designed to use imported raw materials while conserving our own reserves of mineral wealth would be helpful but probably insufficient as a solution to the problem. The import demand for a large number of manufactured items is undoubtedly quite elastic and in some cases the total market is very large. Foreign sellers might undertake to capture a large segment of the American market for textiles, china, cutlery, and other commodities in the production of which the United States has little or no comparative advantage. But the barriers to entry into the American market on a large scale are not simply matters of prices and tariffs. The development of national markets requires years of nation-wide advertising and the establishment of large marketing organizations. It is difficult for foreign countries producing on a relatively small scale to meet the requirements for nation-wide marketing in this country. Government aid in promoting the sale of foreign products on a large scale, would very likely meet with enormous opposition on the part of the American business community. In fact, substantial inroads by foreign competitors which would require a serious retrenchment on the part of any important American industry is almost certain to be met with a demand for the restriction of imports.

We may conclude that in the absence of large American foreign investment or of a commercial policy which will permit large imports of manufactured goods in competition with American producers, the major part of the burden of correcting world disequilibrium must be borne by the rest of the world. General discrimination against dollar imports is probably inevitable until industrial capacity in the rest of the world is considerably expanded and adequate alternative sources of agricultural products for which the rest of the world is now dependent on the United States are developed.

PRICES, MONEY AND THE DISTRIBUTION OF GOODS IN POSTWAR GERMANY

By HORST MENDERSHAUSEN*

In the summer of 1948, the economy of Western Germany underwent a radical change. The change was brought about by a variety of factors. The monetary reform of the 20th of June and the subsequent abandonment of a large part of price and rationing controls re-established money as an effective instrument of purchasing power, and markets as legal and effective devices of allocation. An abnormally good harvest and increased external aid led to a significant rise of food rations¹ and improved supplies of industrial raw materials. But, above all, there came into existence an economy with legal and functioning markets.²

The effect of the monetary and economic measures was impressive. If the Rentenmark of 1923 performed a miracle, the Deutsche Mark of 1948 may be said to have wrought a revolution. Beyond the immediate change in the availability of goods, a significant change in economic relations took place. It was as if money and markets had been invented afresh as reliable media of the division of labor.

During the preceding years there had occurred a genuine regression of economic civilization. Foreign trade had practically ceased and come to be replaced largely by the intake of foreign relief and the outgo of foreign levies. Internal trade had become a most ineffectual system of redistribution by government agencies, overlaid with forms of primeval long-distance trade and local barter, both illegal. Far from

* The author is an economist of the Federal Reserve Bank of New York. During 1947-48, he served with the U. S. Military Government of Germany in the capacity of Assistant Chief of Price Control. He wishes to express his gratitude to Mr. Leander Lovell of the Bipartite Control Office, Frankfurt, Germany, Dr. Eduard Wolf of the Bank Deutscher Laender, Frankfurt, and Miss Erika Teutsch of the Federal Reserve Bank of New York for help and valuable advice in the preparation of this article.

¹ In the bizonal area, the food ration of the normal adult consumer was raised from 1,575 calories per day in June to 1,980 calories in July. In August, it dropped to 1,830 calories; but it remained above 1,800 calories in the later months of 1948. (OMGUS, *Monthly Report of the Military Governor*, Statistical Annex, XVII, August, 1948, p. 19, and later issues.)

² The term "economy with markets" is used here to denote the presence of markets among the legal institutions of the economy. It does not carry any connotation regarding the scope and place of the markets in the economy. "Market economy" (i.e., an economy dominated by markets) and "economy without markets" may be considered speculative extremes. They are theoretical limits to the many combinations of market and non-market patterns of economic life that occupy the full range of economic history.

having been a "market economy" during the 1930's and the war years, the German economy in terms of its legal institutions came close to being an "economy without markets." This regression was as extraordinary to the economic observer as it was painful and bewildering to the people involved in it.

The severe effects of Germany's repressed or stagnant inflation on incentives and production had been widely realized. The index of industrial production in the bizonal area did not reach 50 per cent of 1936 before March, 1948³—it was at 51 per cent in the month of currency reform, June, 1948—while the published indexes of other countries, except Japan, reached levels of at least 66 per cent of prewar, generally better than 75 per cent, in 1947.⁴ But it is far from certain that an earlier imposition of currency reform and an earlier decontrol of prices and commodity flows alone would have caused an earlier and better recovery. In view of the protracted disorganization of government, social life, and foreign supplies, it may be said that economic recovery was hardly within reach before 1948, and that a policy of rigidly suppressed inflation was not more unsatisfactory than any other policy available during that time. Nor would it be proper to limit one's view to the effects of stagnant inflation on production. The listlessness of the economy was accompanied by a dulling of organized social conflict. Market, government, and social conflict had simultaneously and temporarily fallen into disorganization. When decisions were taken to reorganize the economy and the government, the stage was set for progress and for more acute social conflicts.

The economic experience of Germany in the three years since V-E Day contains interesting lessons in the reaction of a modern Western nation to severe economic disorganization. Features of general significance are of course inextricably interwoven with the peculiar facts of post-Hitler Germany. It would be very difficult to separate these components of the situation.

Tenacity of Price Control

Price control and rationing survived the collapse of the Hitler Reich. In November, 1945, the four-power Allied Control Authority resolved to continue the German price laws and regulations and the local and regional agencies for price control, thus reaffirming earlier actions taken by the various zone commanders. On February 7, 1946, the Coordinating Committee of ACA agreed on a statement of price principles applicable in the four zones of occupied Germany and Berlin.

³ Two years earlier in June, 1946, it was 34 per cent of 1936. Revised index published in OMGUS, *Monthly Report of the Military Governor*, August, 1948, p. 98.

⁴ *Monthly Bulletin of Statistics*, Statistical Office of the United Nations, August, 1948.

This was to remain the basic price policy document for more than two years.

This statement provided for the rigid maintenance of the price stop: "As a rule, on the majority of commodities, prices are to be maintained, for the time being, at the level before occupation. Price increases over the level prevailing on the 9th of May 1945 shall only be permitted as an exception. . . ." The need for such exceptions was to be proven by actual losses, after exhaustion of all methods to eliminate cost increases. The possibilities of price relief were further limited by the stipulation that only "average direct cost of production of the aggregate of products of the firm" should be covered, that not more than "the smallest margin for overhead and profits" should be allowed, and by the consideration that "the cumulative effect of all price-increases permitted . . . on the cost of living shall not be so great as to necessitate any adjustment in the present general level of wages."

While these instructions were to guide the German price formation offices in the various zones, the ACA reserved to itself the right to control the prices of the most important basic commodities of industry and agriculture. ACA exercised this function in a most cumbersome and rigid manner.

Within the various occupation zones, the implementation of the price stop policy showed much similarity in form but variation in substance. The Russians used the price squeeze as a means of making private business unprofitable. They exempted from German price law the Soviet corporations that they set up in their zone. In the American zone, price policy was dominated by a "hold-the-line" spirit in the absence of any strong business pressure. The French followed an equally rigid approach while the British vacillated between a Treasury approach of curing inflationary pressure by price increases and a political preference for price-wage stability, the result being a somewhat laxer price stop.

With the formation of bipartite Anglo-American economic policy bodies in late 1946, the principle of the price stop was reaffirmed. In a statement on price, wage, and subsidy policy of November 2, 1946, the Bipartite Board declared that "full expression in prices should not be given to the many temporary and abnormal elements in the present cost structure, especially in the basic commodities, and a limited program of temporary subsidies and stringent control generally is recommended for this purpose." The German price authorities, at the bottom of the hierarchy, reflected the combined influence of Allied policy and German popular opinion. Applications for price increases usually faced long delay and much red tape.

The "price stop with exceptions" was maintained in the face of a

tremendous imbalance of spendable money and available goods. In 1947, currency in circulation in the four zones of Germany and Berlin was estimated at about 10 times the amount that circulated in the Reich in 1936—when Hitler imposed the price stop—total currency and deposits at five times the amount of 1936, while the real national income was put at roughly one-half of that of the Reich of 1936.

Legal prices did increase. The cost-of-living index for the U.S. zone gives a picture of the development of certain legal consumer prices. In October, 1945 this index was only 12 per cent above prewar, but in May, 1948 it had risen to 31 per cent above prewar. While the

October 1947	126	122	193	100	121	159	174	138
May 1948	131	132	193	100	123	165	183	140

^a Computed for worker's family of five, bombed out or evacuated. OMGUS, *Report of the Military Governor*, Statistical Annex XVII, July 1948, p. 49.

weighting and the economic significance of the index are subject to strong reservations; it correctly indicates a relatively small rise during the pre-reform period, very small in view of the exceptional conditions of the country.

The development of the cost-of-living index corresponds roughly to that of average hourly earnings in the industries of the U.S. zone, which were subject to an extension of the pre-occupation wage stop. In March, 1948 average hourly earnings were 131 per cent of 1938. Owing to the considerable curtailment of work hours, however, average weekly gross earnings were only 111 per cent of 1938.⁵

The rise of legal or quasi-legal commodity prices was generally greater than that of the cost-of-living index. In 1947, experts of the British and American occupation authorities prepared estimates of wholesale prices approved or "tolerated" by the German price offices in the bizonal area. The study indicated approximate price developments as shown in Table II.

A new index of basic commodity prices in the bizonal area, established in 1948, showed the prices of basic foodstuffs in mid-June 1948

⁵ OMGUS, *Report of the Military Governor*, Statistical Annex XVII, July, 1948, p. 10.

as 124 per cent of 1938, those of basic industrial materials, as 155 per cent of 1938.^e

The group of manufactured consumers' goods showed the greatest rise, a fact that is also borne out by the lead of new wearing apparel and household furnishings in the cost-of-living index. While manufactured consumers' goods, roughly speaking, doubled in price, agricultural and industrial raw material prices increased by 50 per cent or less.

The resulting change in the price structure, that is, the opening of the price scissors between primary and final producers, was largely due to price control. In the absence of price control, the acute postwar shortage of primary agricultural and industrial goods would probably

TABLE II.—ESTIMATED WHOLESALE PRICE INDEXES IN THE BIZONAL AREA IN MAY 1947, AND COMPARABLE U. S. INDEXES (1938=100)

Products	Bizonal Area	United States ^a
Agricultural products	120 to 125	265
Industrial raw materials and semi-finished products	135 to 145	230
Finished manufactures	190 to 220	177
Producers goods	150 to 180	—
Consumers goods	215 to 240	—

^a Based on the Bureau of Labor Statistics index of wholesale prices for farm products, raw materials and manufactured products.

have put their prices in the lead. That, at least, was the case in the United States. The disruption of the national market in Germany, the lack of imported raw materials, the destruction of the Ruhr industries and the inaccessibility of Silesian coal and Eastern and Central Germany foodstuffs, all would probably have accentuated this tendency.

Price control in Germany produced the inverse tendency, chiefly for two reasons. Price increases of the basic commodities could only be made by the Allied Control Authority itself. That meant in the first place a very laborious process of fact finding and transmitting and finally a sort of four-power conference on the case in hand. The quadripartite negotiations about British proposals to raise the prices of coal and steel showed all the features of futility that have disgraced four-power conferences in recent years. Added to the prevailing price-stop preference among the representatives of at least three of the four powers, this condition prevented anything like a sufficient price adjustment of most basic commodities. It blocked any action on coal and steel.

^e Statistical Office of the Bizonal Area: *Statistische Monatszahlen*, November, 1948, 38. See also Table V below.

into the hands of Allied personnel as their private property (after private importation of cigarettes had been banned); probably 90 per cent of the turnover of existing luxury goods (jewelry, cameras, china, rugs, furniture).¹⁰

Black market operations consisted primarily of transactions in finished products. They usually involved traders and final consumers, to a lesser extent original producers. The products came partly out of German production (typically bread, potatoes, fats, meat, soap, textiles), partly from Allied sources (typically gasoline, tobacco goods, chocolate, certain foods), partly out of personal and household possessions of the German population. They were handled by black market traders, recruited from the ranks of the displaced persons and Germany's unstable and dislocated population.

The contacts between this class and the rest of the population were manifold. People who knew where to buy or sell "black" goods could be found in nearly every house, especially in the larger cities. Every family was involved, at more or less frequent intervals, in the black market sale of some possessions and the purchase of some "black" foods, stimulants, clothing, etc. Characteristically, the excess of expenditures over income in a sample of 81 Bavarian workers' and white collar households (September, 1947), amounting to about one-third of income, was almost entirely balanced by money receipts from the sale of personal property.

Likewise, all business enterprises would at one time or another make a black market purchase or sale to obtain critical materials or parts and to cover costs and tax bills that could not be met out of legal income. But the great majority of households and businesses considered their involvement in black market transactions as shameful, and the agents of the black market as immoral and asocial individuals.

The prices of the black market varied from place to place and fluctuated in time. Owing to bad transportation and communications and to its illegality it was of course an imperfect market, in which some transactions and some places, especially Berlin, would show much higher prices than others. Information collected by the price supervision offices and the police indicated that in May, 1947 black market prices in the main cities of the U.S. zone were about 100 times or more the legal prices for sugar, butter, coffee, saccharine, flour, ladies' stockings, soap, flints; about 75 times the legal prices of oleomargarine, eggs, liquor; about 50 times the legal prices of potatoes,

¹⁰ OMGUS, *Economic Policies, Programs and Requirements in Occupied Germany; Answers to questions submitted by members of the Select Committee on Foreign Aid, House of Representatives, September, 1947*, p. 149 ff.

beef, Leica cameras; about 25 times the legal prices of coal, suits and dresses, electric bulbs, automobile tires and gasoline; and about 10 times the legal prices of typewriters, and electric wire. The most important black market foodstuffs sold at prices in the range of 50 to 150 times the legal level. As a rule, industrial goods had a smaller black market agio, with the notable exception of ladies' stockings, soap and flints. The average of black market prices may be estimated at 50 to 75 times the legal prices.

At that price level, even a small turnover of goods would absorb a large volume of purchasing power. Assuming that only 8 per cent of the total volume of transactions were carried out at that level, while the remaining 92 per cent were carried out at legal prices, the volume of money engaged in the black market transactions would be about five times as great as that engaged in transactions at legal prices. Allowance for the use of money substitutes might lower this figure somewhat; but the order of magnitude would probably remain similar.

In this fashion, the black market absorbed a considerable part of the excess supply of money in postwar Germany. The remainder of the excess was neutralized by the considerable decline in the velocity of money circulation, compared with prewar, that resulted from a variety of factors: the decline of financial transactions, the regression to cash payment and official sterilization policies. Moreover, the excess did not increase; it possibly even declined with time. The slow advance of production and of legal prices probably exceeded any net infusion of money that may have come from the Soviet zone. The fiscal policies followed in the bizonal area whittled away some of the excess purchasing power after 1945. These factors explain in large part the stability or slightly downward tendency in the black market price level during the three years' period.

The black market was limited to commodity and property transactions. Black market wages commensurate with black market prices were practically unknown. Employees working in establishments with obvious black market incomes as a rule preferred compensation in extra goods to extra money, and the same rule usually applied to irregular employment and odd jobs.

Bilateral Exchange

While Germany's postwar inflation remained stagnant in a setting of rigid price control and a stable black market, the distribution of goods and services underwent an important institutional change. Bilateral exchange assumed major proportions. In a large sector of the economy, goods and services could not be obtained for money alone, nor even for money plus ration coupons or allocation certificates. They could

only be obtained on the condition of delivery of other goods and services.

To most people, money did not lose value by way of depreciation but it lost significance through an increasing limitation of its usefulness. Food rations could be bought at legal prices, but it was the ration card, not the money, that controlled the access to the scanty and irregular distribution of foodstuffs. The amount of money that could actually be spent on the food rations was not hard to find. Pegged wages and an occasional black market sale would put that amount into everybody's hands, even without the benefit of former savings. This held true *a fortiori* for other consumer goods. The quantities of clothing and metal goods available after allotments to refugees, and in the latter part of the period, to miners and other workers' groups, were so small that the opportunities to obtain them for money and permits were negligible. The black market, finally, was narrow and an unreliable source of supply for the commodities of daily living, entirely insufficient to obtain the ingredients of production. A mark might be worth half a cent or half a dollar in relative purchasing power; but in either case there was not much of a point in relying on that purchasing power and in laboring to get hold of the mark.

For reliable supplies, businesses, farmers and workers increasingly turned to bilateral exchange via "compensation trade," "distributions to workers," and regular barter. These practices were illegal under the sweeping prohibitions of Nazi wartime legislation, in particular the War Economy Ordinance, which were kept in force under the occupation. But the German and occupation authorities found these breaches of economic controls almost irrepressible. In September, 1947 U.S. Military Government experts believed that from one-third to one-half of all business transactions in the bizonal area proceeded in the form of "compensation trade."¹¹ "At least 50 per cent," was the guess of German government officials in the Ruhr area. This was an all-pervading feature of the economy.

Apart from the limited usefulness of money, two factors helped to establish bilateralism on a broad scale. First, the occupation authorities led the way. In the early days of occupation, local military commanders obtained essential goods for their district by loading up some trucks with the district's products and taking them to the outside suppliers for straight barter. Throughout the period, the occupation authorities offered a ration-free noon-day meal at the legal price to all of their German employees, from top-level expert to street cleaner. This arrangement was the major and indispensable material attraction of

¹¹ OMGUS, *Economic Policies, Programs and Requirements in Occupied Germany*.

service in occupation establishments. Likewise, the occupation authorities introduced "incentives in kind" to boost the economic activities judged most important: coal mining and export production. They thereby acknowledged that in order to buy something you have to sell something to the seller.

Second, in the eyes of most people bilateral exchange was far less immoral than black-marketing. It was usually considered an unfortunate necessity. "How can I keep my workers without putting tires on their bicycles? They will take them, anyway," said the rubber manufacturer. "Everybody knows that to get cement you must offer coal," said the city fathers of Stuttgart, and they bought liquor brewed in the surrounding countryside, shipped it to the French zone in exchange for cigarettes, shipped the cigarettes to a Ruhr mine and swapped them for coal, brought the coal back to a cement plant in Wuerttemberg, and thus got the cement for reconstruction work. The monitored correspondence between two businessmen showed the negotiations preceding certain compensation deals. Their illegality was understood. But when one of the parties demanded an unusually large counter-shipment in return for his products, the second party indignantly charged him with "illegal black-marketing."

Money did enter into "compensation" trade, both as an accounting standard and as a means of payment. Typically, the equivalent quantities of goods in these reciprocal transactions were computed with the help of legal or near-legal prices, the common formula being "peace-time value for peace-time value." From the point of view of price control, many of these transactions were inoffensive. But there also were characteristic changes in equivalencies that reflected the incorrectness of the frozen price structure. For instance, the going rate for the widespread bilateral exchange of cement for coal was one ton of coal for one ton of cement. At legal prices, one ton of coal was the equivalent of one-half ton of cement. The balance due the cement producer at legal prices would usually be settled in money. That was for bookkeeping purposes chiefly.

"Compensation trade" was the typical form of bilateral exchange among industrial producers and wholesale traders. A considerable part of their effort was spent on locating partners to a deal and in arranging for the expeditions needed to carry goods from one place to another safely. The system was costly and cumbersome, and most businessmen disliked it intensely. But it provided a market mechanism, even to the point of developing some clandestine "bourses," and it helped avoid a complete breakdown of industrial activity under the weight of scarcities and trade prohibitions. It is noteworthy that in the more elaborately planned and policed Soviet zone, compensation trade was

not only rampant but even formalized occasionally. A big chemical plant, appropriated by a Soviet corporation, was known to have a detailed list showing the exchange equivalencies of a hundredweight of fertilizer in terms of coal, flour, potatoes and other goods, for the benefit of its customers.

Bilateralism in the employer-employee relationship took the form of factory meals more substantial than the turned-in ration coupons of the workers warranted, the sale of consumers' goods to the workers at legal prices but without permits, and the granting of facilities and materials to "work shops" in the plant, where the workers could make some articles for their own use on company time or after hours. Naturally favored were the employers producing goods of general usefulness to consumers. But where the production was not suitable, or could not be made so by the addition of special lines, goods for distribution to workers were obtained from other producers through "compensation trade," or the workers were given factory products that could be taken out to the peasants and bartered for food. In this way, even a steel mill could satisfy its workers by giving them Thomas fertilizer and steel bands for the wheels of peasant carts.

The pre-commercial system of *Deputate* (payment in kind) that had lived on in German coal mining and on large agricultural estates thus spread throughout the entire industrial economy, chiefly in the form of the provision of facilities to buy at legal prices what was otherwise unobtainable. The 20th century institution of the works' councils, representatives elected by all the workers of a plant, was frequently made the vehicle of the *Deputat* system. The works councils allotted the goods to workers according to some standard of need and they frequently also participated in the procurement of food for the works kitchens.

Finally, there was the direct barter between city dwellers and peasants. The city people hiked to the villages with an assortment of hardware, textiles, tobacco and personal possessions and bartered them for food. In this trading, money played almost no role at all. City people also worked as farm helpers for the food and whatever living quarters were available in the crowded villages.

The bilateral exchange economy was the chief means of survival for businesses and individuals in Germany before currency reform. It developed in the domestic economy to cope with the same basic problem that bilateralism seeks to meet on an international plane, *i.e.*, unreliability of a complex division of labor. Its German variety represents the extreme stage of a development that could be observed in milder forms in the war and postwar economies of Great Britain and the United States. Where neither trading for money nor redistribution

of goods by political authority, alone or in combination, can ensure a reliable division of labor, bilateral exchange seems to be the safest line of economic retreat.

Monetary Reform and Companion Measures

The monetary reform for the Western Occupation zones, introducing the Deutsche Mark¹² as the new legal currency, was ordered by the three military governments on June 20, 1948. Currency holdings and deposits of D-Marks came into existence by (1) the allotment of certain amounts to consumers, businesses, public authorities and military governments, and (2) the conversion of the old marks.¹³ Credit creation soon came to add a third major source of monetary means, and the influx of Western Berlin mark, a fourth and minor source. (See Table III).

The Western zones went into the reform with a money supply estimated at RM 135 billion.¹⁴ On the 7th of September, when the new central bank for the three zones, the Bank Deutscher Laender, gave its first accounting, the economy was equipped with about DM 12 billion on currency and free bank deposits, excluding inter-bank deposits, of which little more than DM 9 billion were created by the reform measures, about DM 3 billion by the bank system through credit creation.¹⁵ Not counting the latter, the money supply was reduced by more than 93 per cent as a result of the reform. These monetary means were to effect the circulation of goods and services at existing or newly forming prices.

It is not intended to give the legal details and a play-by-play account of the currency reform in this article. Regarding its broad economic effects, however, it should be pointed out that the original reduction of money was in effect somewhat more severe than the quoted figures indicate. About DM 1.1 million of the DM 12.3 billion accounted for were nominal accounts and not at the disposal of the economy in September, 1948. Excluding furthermore savings accounts of DM .3 billion, the effective monetary means of the economy were DM 10.9

¹² The basic laws (for the U. S. zone, law No. 61, 62, etc.) have been released by the U. S. Department of the Army, Public Information Division.

¹³ Reichsmark, occupation mark, etc. This division simplifies the more complicated measures that were taken. Technically, the allotments were made in the form of 1 to 1 conversions of old mark into new mark. In later conversions of additional old marks, the customers were debited with nine times the originally allotted amounts in old mark.

¹⁴ OMGUS, *The European Recovery Program*, Joint Report of the U.S. and U.K. Military Governors, September 31, 1948. Little more than RM 100 billion were converted. The remainder was not presented for conversion. The currency reform law provided for the investigation of large old mark accounts.

¹⁵ *Mitteilungen der Bank Deutscher Laender*, No. 13, Frankfurt, October 22, 1948, and direct communications from the same source.

billion, or about 22 per cent of the national income. By comparison, in 1938, the monetary means of the German economy were about 34 per cent of the national income.¹⁸ The shortage of monetary means, however, was offset to some unknown extent by an upward spurt of the velocity of money circulation, reflecting the great propensity to buy in the unfolding markets; and it was rapidly alleviated by credit creation on the part of the banks.

Credit creation on the basis of commercial paper or personal confidence proceeded at a fairly rapid pace till November, 1948, when

measures were taken to check it. The composition of the volume of money by type and by origin at the end of the year 1948 is shown in Table III.

Monetary reform was accompanied by several measures in the field of taxation (the "little tax reform"). The occupation authorities reduced the very high income and property taxes in effect since 1946 by lowering rates and raising exemptions. The corporate income tax was

¹⁸ Money: RM 29.1 billion, national income: RM 85 billion. If savings deposits are included in both years, monetary means amounted to 66 per cent of national income in 1938, 22.5 per cent in September, 1948.

made less progressive. On the other hand, a new high excise tax was imposed on coffee, and local taxes were raised considerably. Contrary to previous plans, however, no action was taken to settle the vast and thorny issue of the "equalization of war and postwar burdens." The occupation powers assigned this task to the German authorities, and the latter have not succeeded so far in finding a solution acceptable to Allied policy makers.

An important companion measure was the adoption of a uniform link between the D-Mark and the dollar, the \$.30 conversion rate. During the year following currency reform this rate gradually replaced the many different "conversion factors" that previously had linked German to foreign prices in export and import transactions.

Fiscal and Economic Policy Pattern since Reform

The development of the Western German economy after monetary reform may be divided into several phases: (1) a brief release phase from the perverted institutions of the war and defeat economy, during which dishoarding dominated the scene; (2) an inflationary recovery phase during which the economy under slack controls advanced toward better performance and produced inflationary tensions. At the time of writing (March, 1949), the German economy seems to have entered a slight recession that may lead to the end of the decontrol period.

A discussion of the price and market developments during the first six months after currency reform presupposes some comment on the shape of fiscal and economic policy pursued by the Allied occupation authorities and the tentative German authorities, whose complicated interaction governed Western Germany during that time.

The German credit system was reactivated by the military governments in a rather quaint form. The central bank system was made irresponsible to political authority, in particular to the central authority that is slowly emerging from the bizonal institutions. In the name of "nonpolitical" finance, the Bank Deutscher Laender was put under the control of provincial political, banking and business interests, and credit policy was placed outside the reach of government. Reflecting an extreme distrust of the economic sensibility of public authority and an inclination to see in government the only conceivable source of monetary maladjustment, the occupation authorities outlawed "fiscal sin": "Expenditures of public authorities must be covered by current income. The procurement of funds by means of credit shall be lawful only in anticipation of future revenues. Military Government reserves to itself the right to intervene in budgetary matters if the maintenance of this principle is imperilled." (Article 28 of the Military Governments'

Conversion Law, promulgated as Law No. 63 in the U.S. Zone in June 1948.)

Put against the background of Western economic experience during the last 20 years, this rigid approach to fiscal policy appears like the ghost that Keynes laid. Its return to Germany has not yet had a chance to produce major social-economic disturbance; but it has not failed to leave characteristic marks on the recovery process of the country since currency reform.

Banking control of the credit volume proved by no means a safeguard against inflation and misdirection of resources. During the first six months of the new system, the commercial banks produced a sufficient amount of short-term credit to sustain a considerable upward movement of commodity prices (see below). Private businesses made extensive use of short-term credits for productive and unproductive purposes, frequently tying up the funds for long periods of time; and whatever power the banks had to influence the use of credit was offset by the wave of cash income that accompanied the liquidation of hoards. In November, 1948, the central bank felt compelled to restrict credit. It chose the means of raising reserve requirements by 50 per cent and freezing the aggregate amount of credit outstanding. The rediscount rate was left at 5 per cent.

The subsequent deflationary pressure was exercised with a similar lack of economic discrimination. What discrimination can be discovered was in favor of those who were indebted to the banks and against new customers or projects. The experience indicated the familiar difficulties of shaping and stabilizing the economic process by relying chiefly on banking measures of one kind or another. These difficulties were increased by the lack of balance between the regional and industrial components of the German economy on the one hand, and on the other hand by the extensive use of cash in business transactions that were meant to escape taxation under existing or expected laws (equalization of war burdens).

Long-term development credit was neglected. The commercial banks concentrated on short-term business. Thus, the weight of credit scarcity fell heavily on new enterprise, in particular such enterprise as could not be financed out of the sale of hoarded goods. It also fell on housing construction, where scarce and expensive credit delayed the removal of one of the narrowest bottlenecks in the German economy, the immobility of labor caused by the lack of housing. A public Reconstruction Loan Corporation was established in October, 1948 to finance long-term projects; but the search for sufficient funds proved very difficult, partly for expected reasons (high spending in all quarters), partly for unexpected reasons (the lack of reserves in the import

counterpart fund). The Corporation remained inactive until April 1949. At that time, a credit program was adopted permitting the application of the Military Government's import counterpart fund to investments in electric power and mining development. No funds were provided for housing.

By barring the German governments from the levers of central bank credit, the occupation authorities severely limited their power to contribute to long-term financing and to the relief of continual (social security) and temporary (unemployment) social needs. These needs are great and varied in the present and in the foreseeable future, the most urgent one being settlement of millions of refugees and immigrants and their economic recovery. Operating under injunction to break even, the households of the eight land governments of the bizonal areas nevertheless showed a deficit of more than DM $\frac{1}{2}$ billion in the second half of 1948, which was met chiefly by drawing down the original allotments of D-Mark.

The problem of the allocation of power over credit is of course tied to the general problem of saving and investment in the economy. It is easy to see that the issue of "thrift *vs.* extravagance" cannot be met simply by putting strings on the government's purse. It is harder to ensure a sufficiently high volume of savings in a socially acceptable form under the circumstances prevailing in Germany. To this basic problem, inflationary recovery under slack controls has not provided an answer. The volume of savings that is currently expected even on most optimistic assumptions, falls far short of estimates of necessary capital formation for essential purposes (DM 6.6 billion for 1949-50). Profit accumulation in many lines of business has been considerable since currency reform; but part of it has been dissipated in unessential investments and purchases of luxuries. At the present time, the problem of making austerity popular and of directing the savings that are forthcoming to essential uses is unsolved. What began as a nominally non-inflationary policy ran into all the social equity problems, if not the economic problems, of inflation because of failure to enforce austerity in a socially acceptable manner.

This failure, however, should not be attributed to a lack of determination on the part of the man who carried the chief executive responsibility for economic policy during the period following monetary reform, Professor Ludwig Erhard, director of the bizonal Office of Economic Administration. Erhard deliberately relied on market forces to enforce greater productivity and savings. It was his policy to make the new markets the vehicle of recovery and to wait for a larger aggregate of income to soften the impact of growing inequality. Within the given difficult setting, lacking power over fiscal policy, and endowed with a

disintegrating and corrupted control machinery, probably no German leadership could have engineered recovery in a less objectionable manner under the circumstances of 1948. But this did not make the economic recovery a social success. The increase of economic inequality between employers and workers, between the native population and the refugees, between the owners of property and goods and the holders of small cash savings put the stamp of inequity on the recovery process and invited irresponsibility and conflict.

Erhard's economic policy may be examined under three headings: (1) re-establishment of markets; (2) slackening of controls; (3) steering of markets.

Re-establishment of Markets

Markets sprang up through the withdrawal of all-comprehensive price, rationing and allocation controls. The extent of this move can be seen in Table IV. Practically all of the listed goods previously had been under allocation and/or rationing and—including the services—under maximum prices, and many of the manufactured articles had practically vanished from the legal markets. Now great hoards of razor blades, kitchen utensils, furniture, bicycles, building materials, home and factory equipment, etc., were disgorged and absorbed by eager buyers.

The re-appearance of legal markets and effective prices was a turbulent process. Prices of the decontrolled commodities ceased to be uniform and stable. Buyers spent their new money freely, held back for fear that the money would give out, spent again when they got more money through conversion or the sale of hoards, bought for fear of rising prices, stopped again under the pressure of lagging incomes from work. The black market was disorganized, at least temporarily, and the new black market that began to form showed a much lower price level than the old. Bilateral exchange went out of existence overnight; but in the fall of 1948 a relapse into the practice was noted in some places.

Slackening of Controls and Price Movements

Not all controls were abolished (see Table IV); but most of those that remained were relaxed by the administration or circumvented by the people. Little was done to provide the crumbling control agencies with new powers or guiding principles. Where controls remained, the black market was permitted to spread and to gain acceptance by the new spirit of "enrichissez-vous." Freed of social opprobrium, it expanded considerably in the field of food distribution.

Two months before currency reform the Anglo-American occupation

authorities permitted coal and basic steel prices to rise. The increases amounted to about two-thirds and one-half, respectively, of previous

 † Free price.

trolled prices, the long delayed adjustment of basic industrial prices to cost increases materialized, and since expansion of production generally tended to lower unit costs, their producers found themselves in a more comfortable price position.

The index numbers, published by the Bizonal Statistical Office (Table V) reflect the extent of the price increases of primary products during the first four months after reform.

Upon decontrol, the prices of most finished industrial goods began to rise. The most significant consumer price increases up to the end of 1948, amounting to a doubling or even greater advance over previous prices, occurred with footwear where they reflected in part increased raw material prices, and with textiles where the prices of imported materials had remained unchanged. In view of the urgent need for shoes and wearing apparel in the population, the great price increases and the weakening of rationing controls over these goods caused much public discontent. The pricing of shoes and textiles out of the reach of industrial workers brought "compensation trade" back on the stage. Toward the end of 1948 there were growing signs of producers making deliveries contingent upon counter-deliveries of wearing apparel, and of their offering the goods to the workers, at reduced prices, in place of wage increases.

The prices of basic foodstuffs have been raised since reform by about as much as the prices of industrial materials. The weighted average of 15 basic foodstuffs in Table V increased by 23 per cent, that of 29 industrial materials by 22 per cent. But food prices have not risen proportionately to the advance of decontrolled *finished* industrial goods. As a result of this discrepancy and the weakness of controls, a considerable expansion of the black market for meat and other foodstuffs seems to have taken place. Despite the excellent crop, official bread grain deliveries in the bizonal area, August through November, 1948, were little higher than during the corresponding months of 1947, "a very bad crop year, and actually lower than in 1946."¹⁷ Supplies were used to feed poultry and cattle, whose products can be sold profitably on the black market. Black market foodstuffs can be obtained generally and easily from retailers at prices two to five times the legal levels.

The reduced price spread and the apparently larger volume of transactions distinguish the post-reform black market from its predecessor. The transition from one price level to the other can be seen in Table VI, which shows the development of legal and black market prices in Hamburg. The data indicate the liquidation boom of

¹⁷ OMGUS: *Monthly Report of the Military Governor*, Statistical Annex XXII, December, 1948, p. 89.

the old black market in the days before June 20th, and the following sharp adjustment. It will be seen that the black market price for coffee temporarily dipped below the legal price after the latter had been raised by a high excise tax.¹⁸

A general black market price index has been reported for six towns in Bavaria.

* Source: Munich Research Office for Economics, quoted in Bipartite Control Office, Price Analysis Section: *Price and Market Developments*, 33rd Report, October 25, 1948.

Following the ideas of "market splitting" that have attracted some interest among German economists,¹⁹ it has been proposed to abolish the compulsion to deliver the entire production of basic foodstuffs at legal prices, and to replace it by quota deliveries at legal prices (the controlled market) and free sales of production in excess of quotas (the free market.) Such a procedure might help sustain deliveries while maintaining the low cost of the basic food ration. But it has not been adopted, since the German authorities felt unable to administer it. The German authorities would have abolished rationing and price control of foodstuffs altogether, if the occupation authorities had not prohibited such a measure.

As a result of these price movements there occurred a noticeable increase of legal living costs. The bizonal cost of living index advanced from 134 per cent of 1938 in June, 1948 to 144 per cent in December; but this index understates the actual increase that occurred in the transition from legal prices before reform to controlled and uncontrolled official prices after reform, if only for the reason that retailers usually quoted nominal prices to the official price collectors. Any true evalua-

¹⁸ This excise tax, imposed under the "little tax reform" of June, 1948, was reduced later in the year.

¹⁹ One of the clearest formulations can be found in a pamphlet by Professor W. Kromphardt, "Marktsplaltung und Kernplanung in der Volkswirtschaft," *Dortmunder Schriften zur Sozialforschung*, No. 3, Hamburg, 1947.

tion of the development of living costs through this period of institutional change would have to allow for the changing volume and price level of the black market. It would probably show an average increase of more than 10 per cent in effective living costs during the second half of 1948.

There was also a noticeable advance of wages during this period. The principle of the general wage stop was maintained after currency reform until the Economic Council resolved to abolish it in October, 1948. But the wage ceiling had been raised shortly before the reform when the Allied authorities permitted wage increases up to 15 per cent of the payrolls involved. These increases were consummated chiefly after the reform and led to a rise of average hourly earnings in industry by 16 per cent from June to December, 1948. Average weekly hours of work increased from 41 to 44, *i.e.*, by 8 per cent, and average weekly earnings by 25 per cent. In December, 1948 the average hourly earnings of industrial workers stood at 141 per cent of 1938.²⁰ Their rise during the second half of 1948 was greater than that of the official cost of living index (9 per cent), but smaller than that of output per man hour in industry (18 per cent).

Steering of Markets

The development of prices and wages stimulated demands for more effective price controls. The trade unions, in particular, opposed the dissolution of the old price control system and demanded the re-establishment of a central price administration. The demand for stricter price controls, possibly assisted by subsidies, may receive further impetus from the increase of the prices of imported foodstuffs that is likely to follow the application of the 30-cents conversion rate to these imports, scheduled to go into effect on May 1, 1949.²¹

Professor Erhard strongly opposed a revival of governmental price controls. A law against extortionate prices was passed by the bizonal Economic Council to placate the opposition. It made the charging of "obviously excessive prices" a penal offense and put a paper weapon into the hands of a paper enforcement agency. In addition, the bizonal administration undertook to publish lists of "normal prices" and ordered merchants to display them in their stores. These lists may have been no less effective in encouraging price increases up to the "normal" levels than in checking high prices. Producers were encour-

²⁰ Statistisches Amt des Vereinigten Wirtschaftsgebietes, *Wirtschaft und Statistik*, Vol. 1 (new series), No. 1 (April, 1949), p. 22.

²¹ Previously, basic foodstuffs brought in under Military Government programs were sold at legal domestic prices, implying a conversion rate of more than 30 cents to the D-Mark. The same holds true for imported seed, fertilizer and medical supplies.

aged to control the wholesale and retail prices of their products. Finally, a program was initiated to make manufacturers produce consumers' goods, especially textiles, at relatively low prices. This so-called "Every-man" program was based on a study of the British "utility" program; but it lacked the strict rationing and price control features of the latter. Rather than a government program, it represents the advance of industrial recovery into the field of cheap, mass-produced consumers' goods after the market for more expensive goods had shown its limits.

In the main, the Erhard administration relied on productivity increases, competition and relatively scarce credit to stop the upward movement of prices and to forestall broad wage increases. Price declines in early 1949 seem to indicate a success of this policy; but they may also foreshadow the end of the decontrol period. The slack of the economy has been taken up and further progress is likely to demand more effective control policies in the fields of distribution, if not prices.

Through the introduction of a uniform conversion rate, the development of prices in Germany has become of significance for her exports, and German prices in turn have come under the influence of foreign price developments through imports. The linking-up of German and foreign prices still is in an experimental stage, with substantial exports leaving the country under special arrangements implying a cheaper D-Mark, and imports, especially of foodstuffs, coming in on terms of implying a dearer D-Mark. In conjunction with the rise of domestic prices, the 30-cents conversion rate tended to discourage exports of various manufactured goods and caused export interests to demand a 27- or 25-cents rate. A lowering of the conversion rate would of course tend to make imported raw materials and foodstuffs more expensive. The occupation authorities, who have exclusive jurisdiction in this matter, have held on to the 30-cents rate for the time being, exploring the problems and watching the pressures affecting the issue.

Performance of the Economy

The substantial recovery of the Western German economy since mid-1948 is apparent from industrial production and foreign trade statistics. Between June and December, 1948, the bizonal index of industrial production rose from 51 per cent of 1936 (same area) to 78 per cent, that is by 53 per cent. Recovery in the producers' goods industries was on the whole somewhat faster than in the consumers' goods industries, with iron and steel production rising from 30 to 51 per cent of 1936, vehicle construction from 26 to 69 per cent, electrical equipment from 81 to 163 per cent; but the advance of such consumers' goods industries as shoes (from 29 to 75 per cent of 1936) and textiles and clothing (from 36 to 59 per cent) was quite remark-

able too. The ratio of current production to that of 1936 in the same area, however, is no measure of the relative level of industrial supplies available, especially on a *per capita* basis. Considerable changes in the structure of industry and trade and the great population increase in the area, among other things, have held that level much below 80 per cent of 1936.

In the field of foreign trade, the second half of 1948 showed a radical improvement of the volume of intake and outgo and a better share of manufactured products in total exports. The excess of merchandise imports over exports, however, remained the same in absolute amount.

^a Chiefly coal and lumber exports.

^b More than three-fifths consisting of coke exports.

The progress of the general efficiency of the Western German economy cannot be assessed as easily as the progress of its gross output. On the one hand the economy rests on the props of American and to a lesser extent British aid, amounting to about \$1.2 billion currently, on an annual basis. On the other hand, it is subject to the drain of occupation costs, amounting to a total of similar if not slightly higher magnitude,²² and a certain amount of leakage caused by smug-

²² For 1947-48, Dr. Eduard Wolf estimated the overt (budgeted) occupation costs, including expenditures for displaced persons, reparations, restitutions and demilitarization, at RM 4.6 billion in the Bizone, RM 5.3 billion in the Trizone. ("Investitionbedarf, Sparvolumen, Zahlungsbilanzausgleich," *Zeitschrift fuer das gesamte Kreditwesen*, October 15, 1948). The current rate of these expenditures was probably lower in early 1949; but it is not likely to have dropped below DM 4 billion, or the equivalent of \$1.3 billion.

gling (capital flight)²³ and the lack of coordinated control over the external trade of the French zone. The prospects of the German balance of payments would of course improve if part of the occupation costs came to be treated as invisible exports, and paid for accordingly, as they are in Austria. Without such an arrangement, the bizonal economy still has a long way to go to raise its exports to the target rate of about \$3 billion (DM 10 billion) for 1952-53, and to reduce its import surplus, particularly with the dollar area, significantly. Along this way, it must expect to find great external obstacles and small rewards in terms of higher living standards.

The economic efficiency of the incipient Western German state is limited by the decay of the body politic that advanced greatly during the Hitler period and that cannot be considered as checked today. The physical recovery that has taken place has given the German society a new lease on life; but neither the new economic institutions nor the external aid that is fed to the system are bound to produce a healthy and peaceful community. The new markets do not necessarily encourage democracy and there is not enough democratic authority to assure fair trading in the markets. It is too early to say whether the economic and social problems opened up by the reforms and the policies of 1948 will be more tractable than the problems that were solved by them. The present experience only shows that the German economy reacted to strong new stimuli after several years of great disorganization, and it proved once more its capacity to produce.

²³ In a press conference on January 26, 1949, General Clay estimated the loss of foreign exchange through smuggling as \$100 to 200 million per year, currently.

The turnover of D-Marks in the Swiss currency markets was reported as DM 1 to 2 million per day at the end of 1948. (*New York Times*, December 27, 1948.) The free exchange rate for the D-Mark on the Zurich market was about \$.07 in mid-October, 1948, \$.14 in mid-April, 1949.

ANALYSIS OF DISSAVING

By GEORGE KATONA*

The analysis of saving by consumers has traditionally been conducted on rather simple lines. On the aggregate level saving, defined as the difference between personal income and consumer expenditures, was usually expressed by one magnitude, either in billion dollars or in per cents of income. It was assumed that the most important variable determining both the amounts saved and the proportions of income saved is the given income level. Numerous investigations confirmed that years of high personal income were characterized by high saving and years of low income by low saving, occasionally even by net dissaving. According to the most recent estimates of the Commerce Department, consumer expenditures exceeded disposable personal income only during the deepest depression, namely in 1932, 1933, and 1934.

Similar considerations were applied when the analysis was made on the level of individual families. The results of expenditure surveys were presented in one continuum. Amounts saved were ranked from the largest saver to the smallest saver, then to the "zero saver" (whose expenditures equalled his income), then to the smallest dissaver, and finally to the largest dissaver. It was sometimes assumed that the large savers were, on the whole, the high-income people, and the dissavers, the low-income people. The dissavers were considered the unfortunate people who were unable to make ends meet and therefore were compelled to reduce their assets (to consume part of their wealth) or to mortgage their future by borrowing. Not only aggregate and average savings were assumed to increase with income, but it was also thought that the higher the income, the larger will be the proportion of the savers and the smaller the proportion of the dissavers.

Are these assumptions generally valid or do we know of any exceptions? More specifically: Is it always true that when income increases, average rates of saving also increase and the proportions of dissavers decrease? The answer is that in 1946 and 1947, in terms of money income, the opposite happened. This is shown in Table I, in which the aggregate computations of the Commerce Department are presented, together with survey data¹ which show distributions of individual

^b Data taken from Surveys of Consumer Finances conducted by Survey Research Center of the University of Michigan for the Board of Governors of the Federal Reserve System. The first survey was made early in 1946, the second, early in 1947, and the third, early in 1948. Each survey was based on a separate representative sample of consumers in continental United States living in private households.

The consumers were grouped in spending units, defined as all related persons living in the same dwelling who pool their incomes for their major expenditures. There are about 15 per cent more spending units than family units.

The amounts saved or dissaved were determined by asking separate questions about each form of saving (change in bank deposits, life insurance premiums, installment purchases, etc.). Positive savers are the units whose income exceeds their expenditures, dissavers the units whose expenditures exceed their income.

The definition of saving as used in the surveys (see *Federal Reserve Bulletin*, August, 1948, pp. 928-29) is not quite the same as that used by the Commerce Department. The most important differences are that the Commerce Department does and the surveys do not include in the savings schedule depreciation on farms and nonfarm homes, and that the surveys include all insurance premium payments, not only additions to insurance reserves. Therefore, aggregate net savings as computed from the surveys are higher than those computed by the Commerce Department. According to the definitions used by both agencies, purchases of consumer durable goods are considered as expenditures and not savings. Finally, additions to and withdrawals from currency holdings are disregarded in the surveys.

^c The total amounts of net savings are taken as 100, and the share of positive savers and of dissavers in that total is shown. The table serves to indicate the relation between amounts saved and dissaved in the three years. It must be kept in mind that the base of each of the three columns is different. The amounts of net savings were much smaller in 1947 and 1946 than in 1945.

families. The aggregate figures show only *net* saving, which represents the difference between amounts saved and amounts dissaved, and they

of Governors of the Federal Reserve System. Reports of the surveys, containing a description of the sample, of interviewing methods, of the reliability of findings, as well as of results, appeared in the *Federal Reserve Bulletin* (see the June, July, and August 1947,

"do not reveal the number of families who spend more than they earn."²

We find that, in dollars, personal income increased both in 1946 and 1947. Yet in 1946 the proportion of consumer units who dissaved increased considerably and the share of total dissavings in the aggregate net savings increased likewise. In 1947 there was hardly any change in the proportion of savers or dissavers, but the share of total dissavings rose further. The amounts saved by the positive savers remained considerable in both years, although they were much smaller than during the war. These data are presented to form the starting point of the analysis. Since they are expressed in terms of money income and do not show the relation of high or low rates of saving to income, they do not necessarily contradict the general assumptions that were described previously.

The most striking development of the years 1946 and 1947 was the increase in the number of dissavers and in the amounts dissaved. Therefore, the relation of consumer saving to income and to other variables will not be analyzed for all American families, but positive savers—the roughly two-thirds of families who spent less than their income—and dissavers—the over one-fourth of the families who spent more than their income—will be studied separately.

Before beginning with this study, attention must be called to the definition of saving used (see also note to Table I). Addition to liquid asset holdings, life insurance premiums, new investment in houses, businesses and securities, and repayment of debt are considered as amounts saved, and the reverse of these transactions as withdrawals from savings. What is most controversial in this definition is that some housing expenditures (additions to and improvements of homes owned) are treated as saving, and that purchases of consumer durable goods are treated as expenditures. If the former were not considered as additions to the permanent wealth of the consumer, the proportion of savers and the amounts saved would have been smaller during the first post-war years; if the latter were considered as such additions, the reverse would have been the case.

The years 1946 and 1947, that are being studied here, are often called "abnormal" years. They are so considered because they follow

and the June, July, August, and September 1948 issues). Most of the data presented in this article have not been published previously. The author of this article was in direct charge of the surveys. He wishes to acknowledge his great indebtedness to his collaborators, both in the Survey Research Center and the Division of Research and Statistics of the Federal Reserve Board. Mr. Joseph Clawson was especially helpful in preparing this article. Those who financed, supervised, and contributed to the surveys are, however, not responsible for the conclusions drawn from survey material in this article.

² *Midyear Economic Report of the President*, July 1948, by the Council of Economic Advisers (Washington, 1948), p. 7.

the war years in which consumers accumulated huge amounts of liquid assets and abstained from buying durable goods and from repairing and improving their homes. Therefore, the developments of these years are sometimes thought unsuitable for the analysis of relationships between economic variables.

Since it is questionable whether any given years ever present "normal" patterns, this argument points to limitations of short-run, cross-section studies. Naturally such studies need to be supplemented by time-series studies extended over many years. But the reverse statement also holds good. One objective of this paper is to show that the usual aggregative time-series studies need to be supplemented by micro-economic short-run analysis.³ The other objective is to shed light on certain trends of the recent past which may affect developments in the near future.

Relation of Positive Saving to Income

The analysis of positive saving appears to confirm the traditional views. The higher the income, the larger was the proportion of positive savers and especially the proportion of large positive savers (units who saved over \$500) in 1946 and 1947. If in addition to the number of positive savers, the amounts saved by them are also taken into account, as is done in the right-hand side of Table II, the differences are more pronounced. Low-income groups accounted for a very small share of the total amounts of positive saving, while the top 10 per cent of income receivers alone saved about one-half of the amounts saved by all people. The sharply accelerated curve of positive saving in relation to income can be seen in Figure 1.

A similar relationship is obtained if instead of all positive saving the two most important forms of saving are considered. Additions to liquid asset holdings (savings bonds, and savings and checking accounts) and savings usually contracted for many years in advance (life insurance premiums, payments into retirement funds, and repayment of mortgage debt) represented during the last two years the most frequent ways of saving, responsible for most of the amounts saved. Both forms of saving gain in frequency when income increases (Table III, Part A). This relationship becomes more pronounced when large amounts of saving are considered.

This does not mean that positive saving is the function of nothing but the given income level. No detailed analysis of the relationship of posi-

³ See the author's paper, "Contribution of Psychological Data to Economic Analysis," *Journal of the American Statistical Association*, Vol. 42, pp. 449 ff., 1947, on the relation between aggregate financial data, micro-economic financial data, and attitudinal and motivational data.

tive saving to other factors will be presented here. Yet it may be noted that many of the variables which show a positive correlation to amounts saved are themselves correlated with income (liquid asset holdings, urban or rural residence, occupation, etc.). By studying the influence of these factors on saving within identical income groups, it appears that certain occupational groups (businessmen, business managers, pro-

TABLE II.—RELATION OF SAVING AND DISSAVING TO INCOME

All Groups	64	28	23	11	100	100	100	100

^a The data indicate, for instance, that among the 10 per cent of spending units who had the lowest incomes in 1947 (whose income before taxes was less than \$750) 41 per cent saved some money, 3 per cent saved over \$500, 25 per cent dissaved, and 12 per cent dissaved over \$500.

^b The total of dollar amounts saved by all positive savers, and the total of dollar amounts dissaved by all dissavers, are taken as 100 per cent; the share of the units in each income decile in these totals is shown.

^c Large positive and large negative savers are defined here as spending units who saved (dissaved) \$500 or more. This definition is used, in preference to defining large savers as units saving a high proportion of their income, because of the importance of large amounts saved and dissaved for the entire economy.

^d Positive savings and dissavings in 1946 are related to income in 1946. The presentation of other data for the year 1946 is omitted; the proportion of spending units in each income decile who saved or dissaved in 1946 shows a similar trend as the proportion who saved or dissaved in 1947.

fessional people, and farm operators) and people in the middle-age groups saved in 1946 and 1947 a somewhat greater proportion of their income than other occupational groups or younger and older people.

Relation of Dissaving to Income

The analysis of dissaving will be carried out in greater detail because dissaving in its relation to income, as well as to other factors, does not present a picture that is the reverse of that of positive saving. First of all, dissaving was unevenly distributed in the various income groups. The statement "the lower the income, the larger the proportion of dissavers," was not confirmed in either 1946 or 1947. Most of the differences in the proportion of units in each income decile who dissaved are so small (Table II) as to be not significant statistically. Only in the

—	—	—	—	—
All Groups	33	14	19	4

^a Spending units who increased their liquid asset holdings and who saved in contractual forms are not necessarily positive savers. Units who reduced their liquid asset holdings and who borrowed are not necessarily dissavers. Some few of the former dissaved through selling houses, businesses or securities. Some of the latter used the money they borrowed or withdrew from liquid assets for investment purposes.

^b Liquid asset holdings include U. S. Savings Bonds and savings and checking accounts with banks, loan associations, credit unions, and postal savings.

^c Premium payments on life insurance, payments into retirement funds, and repayments of mortgage debt.

^d Amounts borrowed on installment and from banks, credit unions, and loan companies. Borrowing money by taking out a mortgage on a newly purchased (or built) house is not included.

highest income decile did the proportion of dissavers drop significantly in 1947, but even this finding is contradicted if large dissavers, instead of all dissavers, are considered.

Similarly, the share of consumer units belonging to each income decile in the total amounts dissaved shows no regularity whatsoever, again in contrast to positive saving. In 1947—not in 1946—it so happens that the lowest and highest income deciles had the two largest shares in the amounts dissaved. The assumption that “the higher the income, the smaller the amounts dissaved” appears to be contradicted.

FIGURE 1. DISTRIBUTION OF INCOME RECEIVED AND AMOUNTS OF POSITIVE AND NEGATIVE SAVINGS BY INCOME DECILES

When, for 1946 and 1947, the amounts dissaved are ranked by the income of the dissavers, the curves are on both sides and close to the line drawn at an angle of 45 degrees (Figure 1), indicating the absence of any marked relationship of either high or low incomes to amounts dissaved.

Dissaving has likewise many forms, some of which were relatively infrequent in the last two years (for instance, net sale of common stock and of real estate, liquidation of business investments). In only two

ways did many families dissave, namely, by reducing their liquid asset holdings and by borrowing. Both forms of dissaving show an irregular relationship to income (Table III, Part B). Consumer borrowing was most frequent in the middle income groups. Large borrowing (over \$500) and also withdrawals from liquid assets appear to increase with income, that is, behave in a way similar to positive saving.

Kinds of Dissaving

In view of these results, it appears necessary to make a new start in the analysis of dissaving. Suppose we abandon the assumption that income level is connected with dissaving; can any other factors be found which may contribute to the explanation of the phenomenon of dissaving? After several attempts governed by economic as well as psychological hypotheses, and after setting up the questionnaire for the 1948 Survey of Consumer Finances in a way that was suitable to investigate certain assumptions, five variables were selected for testing their relation to dissaving.

The first of these variables (see Table IV) is the statement of the head of the consumer unit that he had unusual expenses due to illness or emergencies. The second is the unemployed or retired status of the head of the unit. Thirdly, decline in income was taken into account. The test of the relation between this factor and dissaving was conducted in two steps, once with respect to income declines which, subjectively, were considered temporary and once with respect to all other instances of income decline. Finally, purchases of consumer durable goods, and especially large purchases of such goods, were thought to be related to dissaving because such purchases were frequently financed through drawing on previously accumulated assets or by borrowing, and not out of income.

It may be mentioned at this point that one further variable was investigated concerning its relation to dissaving. This is the amount of liquid asset holdings, the size of U.S. Savings Bonds and savings and checking accounts held (at the beginning of the year). It was found that, of the spending units who had no liquid assets, relatively few dissaved. Naturally, they could not reduce their liquid assets and it appears that most of them also did not, and possibly could not, borrow. But in comparing the holders of small amounts of liquid assets with the holders of large amounts, no significant differences were found in the frequency of dissaving.⁴ Therefore, liquid asset holdings were not

⁴ This negative finding may form the starting point of a study of the relationship of liquid as well as other assets to both dissaving and positive saving. Possibly different results would be obtained if owners of large assets were split into two or more meaningful groups.

their frequency. A similar, though less pronounced relationship holds good for those who had a decline in income and dissaved. Therefore, for these two important groups of dissavers the original assumption has been confirmed: The higher the income, the smaller is the proportion of dissavers. This statement, originally assumed to hold good of all dissavers applies, however, only to those who dissaved under certain circumstances. There are other dissavers who show the opposite behavior. The higher the income, the larger was the proportion of those

TABLE V.—RELATION OF DIFFERENT GROUPS OF DISSAVERS TO INCOME, 1947

Money Income Before Taxes	Percentage distribution of spending units in each income group who:							
	Dis- saver any Amount	Dis- saver Over \$500	Had Illness, Emergency, Unemploy- ment or Re- tirement and		Had Income Decline (Temporary or Other) and		Made Large Purchases of Durable Goods and	
			Dis- saver any Amount	Dis- saver over \$500	Dis- saver any Amount	Dis- saver over \$500	Dis- saver any Amount	Dis- saver over \$500
Under \$1,000	26	9	16	8	11	5	2	1
\$1,000-1,999	31	8	14	5	8	3	4	1
\$2,000-2,999	30	10	12	3	7	3	9	5
\$3,000-3,999	30	12	11	4	6	3	11	6
\$4,000-4,999	30	16	13	7	6	3	13	7
\$5,000-7,499	21	12	6	3	4	2	11	6
\$7,500 & Over	16	13	5	4	4	4	11	8
—	—	—	—	—	—	—	—	—
All Groups	28	11	12	5	7	3	8	4

NOTE: The data indicate, for instance, that 26 per cent of those in the lowest income group were dissavers; 16 per cent of those in the same group were dissavers and had illness; 11 per cent were dissavers and had a decline in income; 2 per cent were dissavers and made large purchases of durable goods. That 16 plus 11 plus 2 exceed 26 is due to duplications within the sub-groups.

dissavers who spent large amounts for the purchase of durable goods. The resultant of the two contradictory trends is shown in the first two columns of Table V where all dissavers are considered and no clear relationship to income is apparent.

Interpretation and Conclusions

Since an association—for instance, between low income on the one hand and the frequency of dissaving and illness on the other hand—does not indicate a causal relationship, no use was made of the concepts of cause and effect in the presentation of the results. But in the following attempt to interpret the findings and to discuss their conse-

quences, it may be permissible to make use of the more common forms of language. It then appears that dissaving may occur under at least three circumstances (or their combinations):

1. Inability to meet "necessary expenses" out of income.
2. Unwillingness to meet "necessary expenses" out of income.
3. Willingness to make unusual expenditures.

First, there are people who, in a given period of time, are unable to cover their expenses for necessities (or their regular expenses) out of income. This may be the case because of illness or emergencies. It may also be the case because of unemployment or decline in income, and even because of certain purchases of durable goods that are considered inevitably necessary. Under these circumstances, some people will dissave. Not all such people will do so, because in the absence of assets and of credit dissaving is not possible. Furthermore, some people will abstain from dissaving even when in dire need and even though they hold assets. It seems that dissaving, because of inability to make ends meet, occurs more frequently among low- than among high-income people.

Secondly, there are people who under certain circumstances are unwilling to keep their living expenses at the level of their income. Typically, when income declines some people will keep up their standards of expenditure for rent, food, etc., even at the expense of drawing on assets or borrowing. Since dissaving was found to be more closely related to "temporary income declines" than to other income declines, it may be said that this behavior will be especially frequent when those whose income declined expect that their income will rise again. Unwillingness to make ends meet may, of course, also occur among retired people whose income had declined at an earlier date and not during the year in which the rate of saving is determined. In view of inflexible expenditures or obligations assumed at an earlier time, it may sometimes be difficult to distinguish the second instance of dissaving from the first.

Thirdly, there are people who decide to make certain unusual expenditures even though they will then spend more than their income in a given period. Purchases of consumer durable goods are a typical example, but large expenditures for vacation trips, or for clothing or luxuries, may lead to the same result. Dissaving, because of large purchases of durable goods, occurred more frequently among high- than among low-income people. Further investigations revealed one of the factors which contributed in 1946 and 1947 to the relatively great frequency of dissaving due to such purposes. More consumer units whose income increased and more units who expected income increases bought durable goods and dissaved than units whose income declined

and units who did not expect income increases. In other words, dissaving of that type was associated with income increases and with optimistic attitudes.⁵

It must be emphasized that dissaving may have several further forms which were not revealed by the current analysis. Also, the indications given in Table IV about the relative size of the various forms of dissaving in 1947 are suggestive at the best. Better methods used in determining the factors that led individual families to dissave may yield different proportions. But the preliminary analysis that was presented here permits us to draw the following conclusions.

First of all, dissaving must be considered a "short-run" or occasional behavior on the part of individual families. Only in one instance, in case of dissaving due to retirement, will it happen typically that a family would dissave for several consecutive years (when the family lives out of previously accumulated assets). It is, of course, also possible that a family with substantial assets would dissave one year because of the purchase of a car, the next year because of the purchase of furniture, the third year because of the purchase of a refrigerator, etc. But such purchases will more often be spaced over many more years or will occur together in the same year (in the year of marriage or the year in which a house was purchased). Moreover, if the dissaving takes the form of buying durable goods on installment, the next period will be typically one of saving since the installment debt must be repaid. Similarly, dissaving due to income decline will not often repeat itself. A decline of income in two consecutive years will probably lead to readjusting expenditure standards during the second year or will destroy the optimistic outlook of the family.

Preliminary investigations appear to confirm these assumptions. When people who dissaved or drew on their liquid assets in 1946 or 1947 were asked about their saving performance during the preceding year and about what they might be doing during the next year, most of them said that they had saved and will save money. The results are not conclusive because of several shortcomings in the methods used. Nevertheless, the following interesting conclusion may be noted: As shown in Table I, in each of the years 1946 and 1947 more than one-fourth of the American consumer units dissaved; it is conceivable that the proportion of those who dissaved in either of the two years was as high as 50 per cent of all units.

Under what conditions will dissaving be frequent and under what conditions will it be infrequent? One kind of dissaving appears to be

⁵ Information on these points and also on the relation of saving and dissaving to income increases and income expectations is contained in the author's article "The Effect of Income Changes on the Rate of Saving," *The Review of Economics and Statistics*, 1949.

a sign of prosperous economic conditions and a factor bringing about such conditions. The higher the income, the more frequent was dissaving due to the purchase of durable goods. Income increases were also associated with such dissaving. Therefore, possibly, the frequency of such dissaving will increase if national income increases. The same might be true with respect to dissaving due to income declines. If the income of a family declines in a year in which most families experience the same fate and national income therefore declines, optimistic income expectations may be infrequent and expenditure standards may be adjusted rather promptly. If, however, the income of a family declines in a prosperous year in contrast to the general trend—19 per cent of the consumer units had lower incomes in 1947 than in 1946—dissaving may be the result in a substantial number of cases.

It is, therefore, not surprising that dissaving was relatively frequent during 1946 and 1947, that is, in years of full employment and high production. The frequent occurrence of dissaving during depression years, as shown by the 1935-1936 Consumer Purchases Study and the Commerce Department tabulations about aggregate personal saving in the early 'thirties, presents, however, new problems. In this respect, it must be recalled that dissaving is not a unitary phenomenon. It is possible that the proportion of families who dissaved is the same in two years, one of which is characterized by high and the other by low business activity, but the functions of dissaving differ greatly in those years. No empirical evidence is available about the kinds of dissaving that are frequent during a depression.⁶

It follows further from the evidence presented in this article that great caution must be exercised in using regression equations expressing the past relation between net saving and income for extrapolating fu-

⁶ J. S. Duesenberry ("Income-Consumption Relations and Their Implications" in *Essays in Honor of Alvin H. Hansen*, New York, 1948) appears to relate dissaving in 1935-1936 to unemployment and to incomes that were low in comparison to previous incomes. This is possible, but as he himself states, cannot be proved on the basis of data available from the Study of Consumer Purchases. Duesenberry's major thesis that "cyclically, the aggregate propensity to consume depends on the ratio of current income to the highest income previously achieved" (pp. 79 ff.) disregards the possibility of a systematic relationship between income increases and the propensity to consume. Also, Duesenberry's statement is probably too broad; the highest income previously achieved may not affect the propensity to consume under all circumstances and in all future years.

We are, however, in full agreement with the major thesis of another recent paper. George Garvy ("The Role of Dissaving in Economic Analysis," *Jour. Pol. Econ.*, Vol. LVI, No. 5 [Oct., 1948], pp. 416 ff.) writes: "There is no logical reason for relating the motivations of two distinct groups of consumers—positive and negative savers—to the same set of causal factors" (p. 416). But in 1947 we found no confirmation for the following statement made by Garvy: "The presence in the population of relatively large groups of families who have suffered a loss of income accounts probably for the bulk of dissaving" (p. 423).

ture trends. Separate extrapolations of the saving and dissaving curves may present a somewhat better analytical tool because it appears to be justified to consider, in a simple model, positive saving as a function of income. But short-run generalizations ought to be based on the factors contributing to positive saving, to dissaving, and to shifts from the one to the other. The survey method appears to be a suitable tool to collect the information needed,⁷ although—and this must be emphasized—the past surveys represent nothing but the start of an analysis of saving behavior. Conducting surveys over many years, adapting survey procedures to the specific objectives of consumer motivation, and using more refined statistical methods (for instance, multiple correlation analysis) may be listed among the requirements of further research.

With respect to the analysis presented in this article, the first requirement looms largest. To what extent are our findings accidental phenomena of the first two postwar years, or phenomena prevailing only in prosperous years? Very little evidence is available to answer that question, especially in view of the possible effects of wartime deferred demand on expenditures in 1946 and 1947. The relationship of dissaving to income must be studied further under different conditions, especially in years in which purchases of consumer durable goods are relatively small. With respect to the possible objection that the analysis was conducted in terms of money income while real income may not have increased in 1946 and in 1947, it may, however, be pointed out that differences in the behavior of upper and lower income groups formed the major source of our conclusions. What is true of differences in the behavior, or of the absence of such differences, of families with high or low money income during the same year applies also to high or low real incomes.

Disregarding theoretical problems, we may attempt to interpret the findings concerning recent past developments. The substantial shift in the consumption-income relation during 1946 and 1947 was accompanied by an increase in the frequency of dissaving. Ability to spend more than one's income was provided by the large liquid asset holdings and the small size of consumer debt outstanding at the end of the war. Willingness to spend more than one's income was provided by the relatively high income level and the optimistic expectations of most families. Some people decided to step up their purchases of goods and services because their income was high and was expected to remain high (and more durable goods became available). Other people de-

⁷ This is also the conclusion of R. V. Rosa; see his article, "Use of the Consumption Function in Short-Run Forecasting," *Rev. Econ. and Stat.*, Vol. XXX, No. 2 (May, 1948), p. 100.

THE EFFECTIVENESS OF THE FEDERAL ANTITRUST LAWS: A SYMPOSIUM

Introduction

Dexter Merriam Keezer*

Recently I asked a company of men who have been closely concerned with the development and enforcement of the federal antitrust laws (primarily as economists and lawyers) to check in broad terms my unhappy impression that "these laws have done relatively little since 1890 to protect and preserve a broadly competitive system."¹ I also asked my correspondents to indicate the principal reasons for their views. I did not address my inquiry to anyone currently charged with official responsibility for antitrust law development and enforcement. The purpose was to avoid any shadow of official optimism, or pessimism, about these laws.

In reply to my inquiry I received a set of communications which seem to me to constitute an illuminating symposium on the antitrust laws. Hence, the communications, edited only to the extent of avoiding unnecessary duplication of the same idea or argument, were cast in the symposium which follows.

It will be observed that the contributions to the symposium vary markedly in length, comprehensiveness of treatment, etc. In seeking them I wrote that it was no part of my intention to burden my correspondents "with making a closely analytical and heavily documented statement" but that a brief summary statement of general impressions would be greatly valued. Consequently, when the contributions are more than this they more than fulfill the request to which they were addressed.

Because of the inevitable lack of uniformity in the contributions it was, of course, suggested that it might reflect unfairly upon the participants who wrote briefer or more hurried statements to have them presented in symposium form. This will not be the case, however, if it is kept very clearly in mind, as it should be, that only a simple, informal statement of impressions was required to meet the specifications set. Also, in retaining the informal character of the communications the vitality of the symposium is, I believe, enhanced.

Since no more certainly effective arrangement of their highly diverse subject matter has manifested itself, the contributions to the symposium are

* The organizer of this symposium is director of the department of economics, McGraw-Hill Publishing Co.

¹ In making my inquiry I explained that I did so "as one who would very much like to see the antitrust laws so enforced as to preserve a pervasively competitive system in the United States." I remarked that "such a system seems to me far more compatible with political freedom than any of the alternative systems of concentrated control, either public or private, which has thus far been developed." I added, however, that I was trying "not to confuse my preference with the realities."

presented in the alphabetical order of the names of their authors. At the conclusion of the individual statements, I have appended a few observations designed to emphasize some of the highlights of the discussion. If they do not succeed in fulfilling this purpose I alone am responsible, as each participant in the symposium has responsibility only for his individual contribution, and for a generous willingness to let it appear as a part of a general discussion of the effectiveness of the federal antitrust laws.

Thurman Arnold

Arnold, Fortas and Porter, Washington, D.C.

The antitrust laws have not been effective in the real world. Therefore, the temptation of an academician is to substitute an administration which looks well on paper and compare it with the antitrust laws as they operate. This seems to me very naïve political thinking. My belief is that the only instrument which has a chance to preserve competition in America is antitrust enforcement through the courts. Traditionally we accept the courts as an institution which cannot be criticized or badgered as we badger an administrative bureau. A grand jury investigation can be conducted without public protest in a way that is impossible for an administrative tribunal to function. That is because there is a judge in a robe sitting over it. An administrative tribunal taking drastic action against a powerful political group cannot survive. We have watched the Labor Board swing too far under union pressure and then we see Congress destroying its public prestige and power. Under our tradition and habits you cannot do that to courts.

Theoretically, of course, there are many other ways to preserve a competitive system. You could arrange a tax system to regulate the amount of business which large concerns may profitably do. For instance, Fred Raymond has worked it all out along these lines in a book, which John Chamberlain endorses, entitled "The Limitist." However, my political guess is that we will not depart from the traditional ways of enforcing antitrust laws.

Unfortunately, all antitrust law enforcement under any plan depends on the public attitude. It does not make much difference what your instrument for carrying out antitrust policy is, it will not be effective unless there is a strong demand. There was such a demand when I was in office.² Today, in an economy entirely dependent on government spending we are sufficiently prosperous that there is little demand. However, I expect the demand to grow as the consequences of the present centralization of economic power make themselves felt in the business world.

² Mr. Arnold was Assistant Attorney General of the United States in charge of antitrust enforcement from March 7, 1938 to March 16, 1943.

Wendell Berge

Posner, Berge, Fox and Arent, Washington, D.C.

The antitrust laws have not stopped the trend toward concentration of economic power, which today is greater than ever. That concentration threatens our continued prosperity and, indeed, the very existence of what we think of as a capitalistic system. It also threatens our free political institutions.

Why have the antitrust laws failed in their basic purpose? In my judgment, it is because we have never really made an "all-out" effort to enforce them. The funds appropriated for antitrust enforcement have never been adequate nor has the enforcement staff ever been equal to the job. Often the will to enforce has been lacking.

I do not think that there is any fundamental weakness in the laws themselves, although, of course, implementing legislation is necessary from time to time. I think that in the Sherman and Clayton Acts we have the legal weapons which could be effectively employed to reverse present monopolistic trends, if we had the will and the resources to use those laws to the utmost.

Is there any reasonable chance that revitalization of antitrust enforcement will become a cornerstone of new national policy? The answer depends, I believe, on the extent to which independent business and the general public become aroused to the acuteness of the problem. The next few years will tell the story. There are some favorable signs, but it is too early to make any confident prediction. If we do not move toward vigorous termination of monopoly power over American industry, it seems to me inevitable that we shall find ourselves in less than another generation with some form of government-controlled and socialized economy.

Arthur R. Burns

Columbia University

Although federal antitrust legislation has been on the books since 1890, there is very little doubt that we have failed to achieve a competitive system at all closely resembling that which was in the minds of the economists of the last century and which provided the background for the legislation. The reasons for this failure lie partly in the forces within the economic system operating in a contrary direction to the legislation and partly to difficulties of achieving competition by law.

The primary pressure away from an organization of industry likely to operate competitively is the industrial technique of production. This technique often requires plants of considerable size for most economical operations. Where considerations affecting the most economical location of industry involve the scattering of plants throughout the country, local monopolies tend to develop from this cause alone. Even in other industries relatively few plants sometimes emerge as a result of efforts toward the most economical scale of operation.

The fact that a considerable part of the costs of industrial production are fixed (the proportion varying widely, however, from industry to industry) permits price-cutting of the short-run type to drive prices down sometimes to the point at which they cover only marginal costs well below average costs. The fact that the industrial technique also involves investments with a considerable physical life means that prices can stay at these levels for considerable periods. However desirable this situation may be in broad economic terms, businessmen, pursuing the profit motive, seek to avoid it. Where they are relatively few, they can pursue their interest by coming to agreements or by price leadership. Alternatively, firms may bring under common control plants at a number of different production points. Thus, the firm may be considerably larger than the plant of the most economical size.

In other circumstances, and particularly in the sale of consumer goods, there is a tendency to turn to the differentiation of products and the use of promotion expenditures, particularly on advertising. Consequently, considerations as to the size of the most economical distributive and promotional organization begin to affect the size of firms and again firms may be larger than the smallest plant capacity capable of production at minimum cost. Thus, there are various forces making for large firms and larger firms mean fewer firms. Tariffs tend to reduce further the number of sellers in industries which are effectively protected from foreign competition.

There has also been a number of forces operating to increase the size of firms by increasing the variety of their activities as well as the scale of their operations in any one activity. The resulting patterns of integration are varied. Vertical integration seems to occur sometimes as a solution to otherwise insoluble problems resulting when at some stage of production there are not only few sellers but also few buyers. During the last twenty-five years the organization of retailing in this country has been passing through a revolution, as a result of which numbers of small retailers have been replaced by large organizations which, in order to be large, are also territorially integrated. But the price competition which resulted at the retail level has brought forth efforts on the part of manufacturers to protect themselves from the direct or indirect pressure of price competition at the retail stage. In some industries such as oil, manufacturers have become integrated through to the retail level. In others, manufacturers have sought (in their own interest, or under pressure from that section of retailers which fears that it is about to be superseded) indirect methods of integration, more particularly through resale price maintenance contracts.

From the point of view of social control, the major question is why a law aiming at the suppression of restraint of trade and monopolies has failed to place an effective barrier in the way of many of the foregoing tendencies generated by the industrial process of production.

The most fundamental reason for the considerable measure of failure of efforts to erect such a barrier lies in the inadequacy of the economic theory underlying the legislation. Theoretically, perfect competition results in the ideal allocation of resources among uses; in a general tendency for costs to cover only the costs of the most efficient firm in the long run, and for full

capacity to be utilized except when the resulting prices fail to cover marginal costs of production. But the theory is internally contradictory in some circumstances. The lowest cost may be achieved only by firms so large that they are too few to behave competitively. A choice must then be made between (1) firms of the most efficient size but operating under conditions where there is inadequate pressure to compel the firms to continue to be efficient and pass on to the consumer the benefits of efficiency and (2) a system in which the firms are numerous enough to be competitive but too small to be efficient. The courts faced with this choice have been either unwilling or unable to decide between the two horns of the dilemma. The dictum in the United States Steel Corporation case that "mere size is no offense" seems to rest upon a choice of efficiency with whatever size it may involve. Irrespective of the facts in the case regarding the most efficient size for the corporation, the court was unwilling to obstruct businessmen in the pursuit of efficiency, whatever the result as to the competitiveness of the market.

Furthermore, had the courts been willing to choose the other horn of the dilemma, namely the maintenance of enough firms to insure competition, they would have faced further difficulties in the solution of which they would not have found economists very helpful. More particularly, the number of firms necessary for the maintenance of competition is a problem that has never been satisfactorily solved, and a firm operating under a ceiling as to size cannot be expected to be fully competitive.

Facing these difficulties, the courts have been unwilling to interfere where they could find plausible reasons for keeping out of complicated difficulties. They have often made their choice as to whether or not to interfere on the basis of a judgment of the motives of businessmen. The reason for this attitude lies largely in the belief that if the market tactics or merger policies under review seem to them to be aimed at the elimination of rivals as a means to attaining a monopoly, or where there is direct evidence of such motive, interference is unlikely to impede efforts to attain efficiency. The fact that some of the prosecutions have been under the criminal clauses of the law tends, for reasons of legal tradition, to place emphasis on the motives of those under indictment. While this policy is not in itself unreasonable, it has two fundamental defects impeding the attainment of competition. First, the determination of motive is extremely difficult and, in actual market situations, may be almost impossible. Second, motive itself is, from the economic point of view, secondary. Those who desire to see the antitrust laws enforced aim ultimately at the maintenance of a competitive structure whether it is threatened by people whose motives are good or bad.

Where oligopoly already exists, economic conditions have not by their nature compelled competitive behavior. The effort to maintain competitive behavior under these conditions seems to be doomed to failure. If businessmen choose price leadership as a means of avoiding price competition, no legal device has yet been discovered by which leadership can be prevented, except perhaps where it is based on collusion. There is no form of decree that can be addressed to a leader by which he can be prevented from being accepted as a leader. It would be more appropriate to address such a decree to

the price followers. But a decree preventing them from charging the same price as the biggest firm in the industry would not be feasible, and might also be rejected as unconstitutional. The same difficulties attend efforts to eliminate basing point systems. The firms in an industry may be ordered to cease and desist from the use of such a system, and possibly the non-base producer may be compelled to adopt a base price of his own. But it is not feasible to determine the height of his base price which, in fact, determines how nearly he remains a non-base producer. The requirement that producers sell to all buyers as a production point at a uniform mill price may eliminate competition by interpenetration of market territories but it remains to be seen whether competition in mill prices will be intensified, whether such prices will be lower than under a basing point system and the extent to which the delivered price of the product may be higher when demand in the vicinity of a producing point exceeds the capacity there. Economists have not been able to suggest any generally acceptable territorial pattern of prices.

Similar difficulties attend efforts to attack another important policy that has emerged from oligopoly, namely the price set and maintained at a stable level for considerable periods of time. Decrees to compel firms to change their prices from time to time are hardly feasible, because of the necessity for prescribing the frequency, and presumably also the amount of change that will comply with the requirements of the court. Here again the economist has been unable to establish criteria which would give the courts confidence in making such decrees.

If the courts do not accept monopoly or oligopoly, they are then faced with the necessity for determining the number of firms to be maintained in order to remove these conditions. In the past, they have from time to time broken up the almost single-firm monopoly but largely because they were persuaded that these monopolies had been achieved, not as the result of a quest for efficiency, but rather in the effort to achieve control of the market. Even so, they have never done more than replace almost unitary monopoly with oligopoly. If they did seek to eliminate oligopoly, they would encounter the difficulties already mentioned concerning the criteria as to the number of firms necessary for competition.

The courts have also been somewhat confused by repeated, and generally truthful, statements by business that it faces considerable competition. The difficulty here lies in the fact that competition or rivalry can take a great variety of forms ranging from the physical destruction of a rival's plant or products to pure price competition. Each of the available types of competition has its own peculiar consequences, some of them varying according to the nature of the industry. Only pure price competition can produce the results which most people have in mind when they defend what they call in general terms "the competitive system." Non-price competition by way of product differentiation and sales promotion operates to increase costs rather than reduce prices. But consumers may benefit to some extent from increased expenditures, particularly on product differentiation or quality competition. Consequently, judgment of these types of competition is extremely difficult. Here again the economist is unable to be very helpful to the court because

typically where an oligopoly engages in product differentiation and service competition, the buyer has no choice as between various combinations of price, quality, service, and the like.

The foregoing does not mean that the antitrust laws have had no effect. It is customary to say that they must have had some preventive effect. The probabilities are that this statement is true, although by its nature it is unprovable. Consequently, no measure of the preventive effect can be available.

The recent modifications of the antitrust laws give considerable general support to the court in its extremely cautious attitude regarding the disturbance of existing business structures and market behavior. The legalization of resale price maintenance provides an opportunity for businessmen to prevent price competition at retail. The court is justified, therefore, in believing that Congress is not determined to maintain price competition wherever it may occur and in this case in the market for consumers goods. State legislation imposing discriminatory taxes on chain stores can be interpreted by the courts as an indication that at least the state legislators are not in all circumstances ready to permit reorganizations of business producing greater efficiency as measured by costs. The Robinson-Patman Act regarding price discrimination rests in the main upon criteria of price discrimination drawn from much economic writing. Here again the courts must realize that this legislation is a part of the struggle between the older and newer organizations in distribution in which the older group sought protection from the state presumably because it was not prepared to rely on the outcome of competition. It is stated, however, that in these circumstances competition is not likely to produce the most desirable results because the very large buyer obtains advantages accruing not only from his cost-reducing opportunities but also from his market-control opportunities. While there may be truth in this statement, it has never been very satisfactorily documented and in practice it is almost impossible to draw a line between the two sources of possible price reduction.

Frank Albert Fetter*

Princeton University

In the tug of war between competition and monopoly in the United States, "the free competitive system" has on the whole, I fear, lost ground, but the end is not yet.

Among the influences tending to make the antitrust laws relatively ineffective are: the fundamental change in the business corporation laws beginning about the time of the passage of the Sherman Act, whereby it became legal for one corporation to acquire and hold the stock of another corporation,

* Dr. Fetter, professor emeritus of political economy at Princeton, died on March 21, 1949. Consequently, his part in this symposium constitutes the last of his many distinguished contributions to scholarly literature on the federal antitrust laws and their enforcement.

thereby pretty effectively defeating the purpose of that act; the approval by the courts of this mode of whittling away and destroying competition definitively in large sectors of the economy; the consequent limitation of the Sherman Act to the prosecution of explicit agreements in restraint of commerce, with the result, as has been repeatedly shown, of putting a premium on absolute merger, the most complete mode of abolishing competition; vague and ambiguous terms in the antitrust laws which, it matters not how they came to be there, have long been an insuperable obstacle to enforcement; the neglect by Congress to seek much needed aid of a technical nature in the framing of economic legislation; the pressure of organized special interests and skilled lobbyists in such legislation; the expenditure by corporations of lavish sums to defeat the enforcement of the antitrust laws, sums much greater than those spent by the government in their enforcement; and the extensive employment of academic economists in defense of monopoly. These are simply the main counts in the explanation of the relative inefficiency of the antitrust laws.

The most noteworthy influences tending to enlarge the possibility of free competition have been the utility investigation in the 'thirties; the holding company act; the creation and operation of the Security Exchange Commission; the more vigorous enforcement of the Sherman Act begun by Thurman Arnold and continued by his successors; the increased insight of the Supreme Court into the economic aspects of the problem; the recent basing point decisions; the activities of the Federal Trade Commission; and the awakened public realization that "a pervasively competitive economic system" is alone compatible in the long run with political freedom. This proposition is at least given lip service by many who still are striving to retain and increase monopoly control in their own industries, and thus are helping to dig the grave of a truly democratic capitalism.

We are listening to a great deal of naïve hypocrisy about the need to preserve our perfect system of free competition. Concentrated control has already gone far and is going farther.

Theodore J. Kreps

Stanford University

I am disposed on balance to agree that the antitrust laws, as interpreted and enforced, have neither stopped business aggrandizement nor preserved, in so far as it existed, a "broadly competitive system." I doubt whether by themselves they could have done so, even had they been fully enforced. It is certain that the amount of monopoly, whatever that may mean, is not less now than in 1890.

The antitrust laws probably have had more of a prophylactic than a remedial effect. The onward sweep of technological agglomeration has not been delayed. To avoid the risk and cost of antitrust litigation businessmen may, on occasion, have reluctantly dropped or modified highly cherished

plans or operations. No doubt the extra ingenuity required to revise old methods or devise new ones has been irksome. Even when they achieved their ultimate goal and purpose, they resented the fancied or real interposition of legal obstacles. A small but important percentage has been annoyed. Thus, periodically there has come into public print a rash of complaints about "vague uncertainties" in the act, lack of "positive definition," "arbitrary" enforcement activity, "unpredictable" court demarcations of the scope of the law, and the like.

But, by and large, most businessmen—that is, all but a small fraction of our 3,500,000 enterprises—have always realized that nothing in the antitrust laws forbade vigorous, independent competition. Like good pilots who safely bring their ships into port by knowing where the deep water is, the conscientious businessmen have not needed nor asked for blueprints mapping out every shoal of "non-permissible practice." They have simply gone ahead competing vigorously for customer patronage.

The squeaking axle, however, naturally gets the grease. Overwhelming in number as were the competing enterprisers, many of them operating on a large scale, the proportion of output produced, transported, and distributed by them was not commensurately large. Steadily in one industry after another, technological and financial giants captured more and more of the market. The few "million-dollar-trusts" that scared the public in 1890 look like pigmies now alongside the famous "two hundred" spotlighted by Berle and Means or the half a hundred or more billionaire corporations that dominate finance and industry today.

Such giants are not only found in banking, insurance, railways, public utilities and natural monopolies. Whatever may be the causes—technological efficiency, high finance, two World Wars, or what have you—more than a third of the total value of all products even in the field of manufacturing is produced in industries where the four largest producers account for over 75 per cent of national output. Almost another third is produced in industries where the four largest firms account for more than half, though less than three-fourths of total production. Nor is the movement limited to basic industries. Recent studies of mergers by the Federal Trade Commission document a widespread "swallowing up" of independent competitors in the textile, food, and distributive trades.

Clearly the antitrust laws have not preserved competition. In fact, it is doubtful whether during most of the period since 1890 Congress has actively so desired. While its oratory has been "agin monopoly," its acts have steadily exempted one industry or practice after another from compliance; farm marketing associations, labor unions, shipping, banking, etc. The legalization of price-fixing in the Miller-Tydings Act and the *carte blanche* given to railway executives in the Bulwinkle Act are but recent flagrant examples. But for the election upset, legalization of basing point and formula pricing and/or exemption of insurance executives might have come next.

Despite a quarter of a century of reiterated pleading from its Federal Trade Commission to close the loopholes in Sections 7 and 11 of the Clayton Act, Congress has done nothing to prevent merger by sale of assets. No

hindrance has been placed upon vertical and lateral integration. The "gobbling up" of competitors ravages on unchecked.

Congress has disregarded all suggestions to strengthen the law. One of its more important investigating bodies, the Temporary National Economic Committee, thoroughly examined and documented the case for many much needed improvements. It urged a statute imposing civil penalties which would deprive a monopoly of its monopolistic gains. This would have eliminated the humiliating spectacle presented in the Hartford-Empire case wherein the Supreme Court found flagrant abuse of patent privileges but felt constrained to let the violator in effect "keep the swag."

Congress has similarly failed to act on a number of bills, presented by such intelligent and far-sighted statesmen as Senator Joseph C. O'Mahoney of Wyoming, which would put teeth into the antitrust laws. Instead of the present piffling penalties, which are so low as to constitute at most a good business risk, Congress has refused to authorize fines on individuals and corporations that would genuinely deter deliberate and repeated violation—fines equalling, for example, half or more of the net profits earned by the corporation, or salary earned by the persons, during the period it was, or they were, violating the law. Some have suggested penalties upon convicted executives barring any organization in which they hold a responsible executive position from obtaining governmental aid, subsidies, tariffs, patent grants, purchase contracts, mediation or other benefits. Congress has not considered the matter.

Likewise, Congress has not required the registration of international cartel agreements. Were there a sanguine interest in devising means of buttressing the antitrust laws, there might have been resort to a number of other expedients such as taking the tariff off commodities produced under "conditions of oligopoly and monopoly," repealing the Webb-Pomerene Act, ratifying the ITO charter, revising the patent laws so as to prevent monopolistic abuses, fostering and mobilizing technological research nationally, and inaugurating a program of aid to small and new business. Such a program might be similar to that now operating in the field of agriculture, a program of diffusion of information, research and technical assistance, financial backing, and appropriately modified taxation. To all such proposals Congress has thus far turned a deaf ear.

Until recently the courts have also done their share in impairing the vigor of the antitrust laws. By emphasizing legalisms such as formal proof of "meeting of minds," they have struck down weaker and sometimes innocuous types of agreement between independent producers while giving a clean bill of health to corporate giants by such judicial inventions as the "rule of reason," and doctrines that "mere size is no offense" and "not existence but abuse of monopoly power must be proved." Thus a colossus such as the Aluminum Corporation of America, the classic example of monopoly, was allowed without even the initiation of government complaint (until 1937) to "stabilize prices," "adjust production to consumption" and "prevent market demoralization and chaos," while scores of tenuous arrangements between small producers in

and out of trade associations were struck down as conspiracies in restraint of trade.

The record of emasculation in *U.S. v. E. C. Knight Co.*, *Standard Oil Co. v. U.S.* (1911), *U.S. v. United States Steel Corporation* (1920), *Arrow-Hart and Hegeman Electric Co. v. Federal Trade Commission*, and similar cases is well known. Fortunately the record has been conspicuously improved in recent years by such notable decisions strengthening the antitrust laws as *Morton Salt Co. v. G. S. Suppiger Co.*, *U. S. v. Aluminum Corporation of America*, and in particular the opinion of Justice Burton in *American Tobacco Co. v. United States* (66 Supreme Court 1125, U.S. 1946). This case, according to Professor Rostow in his *National Policy for the Oil Industry* (p. 137), clearly means that henceforth

Painstaking search for scraps of evidence with a conspiratorial atmosphere are (*sic*) no longer necessary. . . . Under the Tobacco case, the economic fact of monopoly is very close to being the legal proof of monopoly. . . . Parallel action, price leadership, a reliance on advertising rather than price competition as a means of inducing changes in each seller's share of the market and, above all, size—the market position of a small number of large sellers or buyers—these are now key points to be proved in a case of monopoly, or of combination in restraint of trade. . . . The decisive elements are the power to assert a degree of control over price and output in the market as a whole, and the power to deter or discourage potential competition.

Future decisions of the Supreme Court, may, of course, depart widely from the direction and outlines of Professor Rostow's interpretation, but if they do not, the impact of the antitrust laws upon monopoly may be substantial.

On the administrative side, except for the sincere and brilliant efforts of Thurman Arnold and Wendell Berge (under whose administrations more cases were filed and won than in the entire remaining lifetime of the antitrust act), over-all enforcement of the antitrust laws has been conspicuously weak. The federal government has been a policeman who looked the other way.

At no time have appropriations been remotely commensurate with the job to be done, nor have they ever been asked for. Even in 1939, the Anti-Trust Division spent less than \$800,000 and the Federal Trade Commission slightly less than \$2,200,000. In 1946, the sum-total appropriated for these agencies was still under four million dollars. A nation that spent more than 100 billion dollars in one year to defend its system of free enterprise against a foreign enemy devotes to protecting the system against monopoly less than enough to have financed its war effort for 25 minutes.

No wonder antitrust cases have not been pushed through with speed. In 1946, a sample of 41 out of 435 cases filed in the eight years from 1937-1945 showed four had been pending for more than seven years, and six for more than five years. Even the Federal Trade Commission which was given administrative powers precisely so that justice might be dispensed with dispatch, often requires over three years and has been known to take as long as eight years to push its cases to completion.

Coupled with lack of money, the major reason for these shortcomings is insufficient personnel not only in numbers but in competence. Both political

parties have observed long since that the persons likely to run afoul the anti-trust laws are not the ordinary socially ostracized criminals but rather the more respectable, powerful and wealthy businessmen, those most likely to command not only dollars but newspapers and votes, and often indeed Congressmen. Zeal, initiative and resourcefulness in enforcing the antitrust laws are likely to be much more embarrassing virtues in an administrator than obsequious caution, meticulous solicitude for congressional and public relations, and indefatigable insistence that every protection of procedure or evidence be given the defendant.

Because of such stultification, particularly when intensified by witch hunts and by business-fomented contempt for "bureaucrats" and "tax eaters," lawyers and economists of integrity, objectivity and vigorous independence of thought usually prefer almost any type of employment to working for government. Those who plan to use government service as a stepping stone soon discover that skill and productivity in developing civil suits and criminal indictments (and what's worse, ability to make them stick) are qualities not highly conducive to making the "right friends" and influencing the "right people."

The effective and conscientious lawyer or division chief in antitrust agencies may find himself somewhat alone—first of all, in court. In the cement case there were three FTC attorneys pitted against 41 of the largest and most successful law firms in the country. In the Madison Oil case there were five for the government against 103 protectors of oil. Higher government echelons, moreover, may not be grateful for his contribution to their administrative headaches. He is also likely not to receive invitations to participate in those numerous important informal government-business policy get-togethers so indispensable to intelligent law-making and cooperative, effective administration. He thus finds antitrust activity to be attended with some measure of risk of damage to his reputation and career. These factors (plus in some cases social coventry or failure to "make" important social affairs given by the "best people" and higher-ups) cause high turnover of conscientious personnel at lower levels, while those too important to be let go even with a transparently flattering letter are often "kicked upstairs," sometimes graduated into judicial eminence.

There are, of course, a large number for whom government service is just a job. If they were too naïve to have realized the fact in advance, they soon learn that a high reputation among businessmen for constructive and understanding public service usually is acquired by excelling in those government activities through which favors are ladled out. It's a much shorter step into lucrative business posts and honorific university assignments from a War Production Board, Reconstruction Finance Corporation, or the Departments of War, Navy, Commerce, and State than it is from antitrust. Consequently, those who are ambitious and, needless to say, those content with a long, serene career in regulatory agencies, wisely follow the tactic of being spineless chair-warmers, never "sticking out their necks."

Even if personnel in the antitrust agencies feel sufficiently rewarded for their industrious activity by the consciousness of arduous duty done, there

are those in other governmental departments who do not fully share the glow. Violators of the antitrust laws often find many a sympathetic shoulder there to cry on. I know of no instance in which because of difficulties with antitrust, businessmen ever lost out on a government contract, research grant, subsidy, tariff or other favor. In some cases they have been given not only effective support but active assistance in building political backfires at both ends of Pennsylvania Avenue.

In too many instances such treatment of antitrust (as a competitor in the classical sense; one with whom one has no friendly dealings) is due not merely to normal bureaucratic preoccupation with intra-agency problems and inter-agency knifing. It also stems from the fact that Congress has imposed responsibilities the discharge of which is made difficult, if not impossible, except by "playing ball" with enterprises so large as to be enmeshed in practices contrary to the antitrust laws. During the war procurement officials would have been helpless without the active cooperation of big businesses. To whom else could research funds be allocated? In short, there are sometimes goals superior to uncompromising enforcement of the antitrust laws.

Precisely because "nobody loves the cop," antitrust agencies prefer to initiate cases on the basis of complaints. While only a fraction are acted upon, such cases are not only most likely to be easiest to win but to be most productive of political support and larger appropriations, with subsequent policing of the outlawed practice automatically enforced by business itself.

Unfortunately, there are many instances in which businessmen, all of them by no means small, are afraid to complain or refuse to testify and provide evidence, or do so only after making pitifully certain that guarantees of secrecy and anonymity are adequate. Monopolistic practices in such cases are often precisely the most vicious and strong. What can the administrator do? Forget about it? Challenge the powerful industrial police system? Or find a face-saving formula?

The most palatable solution is, of course, a maximum appearance of enforcement with minimum actual alteration in highly profitable practice. Hence the emphasis on legal victories which look good in annual reports and budget hearings, even though many are almost completely empty so far as the actual breaking up of a monopoly or the elimination in reality of that which was achieved by a monopolistic practice is concerned. It may be acute fear of making this discovery that accounts for the happenstance that none of the antitrust agencies has ever systematically followed up its cases to find out how far actual business operations had been changed. Frequently the only result, as Professor Rostow has indicated in the Socony-Vacuum and Ethyl Gasoline cases, is the invention of substitute legal devices leaving the basic monopolistic economic activity undisturbed.

It is easy to exhort the antitrust agencies to cut loose from the political support of those who dare to complain, and urge it to spend its limited funds for systematic surveys of concentration of economic power, industry by industry, and then to proceed to take action against the most important areas of concentration even though not a single congressman or other representative of the government has received a single complaint. It is easy to

find fault with antitrust for accepting pleas of *nolo contendere* and consent decrees, rather than fighting dissolution suits through to Supreme Court determination. The power of pressure groups being what it is, it is also futile.

In the organic sense of the term there is but little genuine support for enforcement of the antitrust laws. Certainly, buyers like competition among their sellers and *vice versa*. But it is not enough that a person want the antitrust laws enforced against other people. Does he support enforcement against himself and others in his industry? Or does he know a hundred and one reasons why monopolistic practices, while evil elsewhere, are nonexistent or harmless in *his* business? If the latter case, he cannot be said to oppose monopoly any more than a person who believes that all prices except his own are too high can be said to oppose inflation. Such groups—farm organizations, labor unions, retailers, manufacturers' associations, etc.—in short, all groups that tolerate only so much competition as they cannot prevent, believe, in effect, neither in the antitrust laws nor in free enterprise. They abet and foster monopoly and inflation.

Yet a coordinated policy designed to preserve and enlarge that which remains of a "broadly competitive economy" requires coordinated action throughout business, labor, agriculture, and government. President Roosevelt in his message on the TNEC, Senators O'Mahoney, Kefauver, Kilgore, and Morse in a series of antimonopoly bills, The Twentieth Century Fund in its studies on cartels and competition—these point the road most likely to achieve the goals of the Sherman Act.

For such a coordinated attack on monopoly, the first requirement is a coordinated, flexible adaptation of policy and tactics to over-all economic conditions and needs, which in turn requires a full-fledged Bureau of Industrial Economics serving as an economic intelligence agency for government as a whole. In a TNEC monograph on *Measurement of Social Performance of Business* I have suggested some vital functions and activities for such an agency, emphasized the indispensability of information, corporation by corporation, if a beginning is to be made toward successful enforcement of the antitrust laws. I have also outlined some rudimentary though as yet unsatisfactory methods for making a social audit of the performance not only of individual industries but of particular business corporations. The important fact, then as now, it seems to me, is not the size or number of producers but their social performance. It is not competition *per se*, but the benefits of competition, that is, maximum freedom of enterprise including freedom from the fear of abundance, maximum production at minimum real costs and prices, maximum real income and employment. What is the pattern of performance of the industry or business as a whole?

Such information is rarely sought and never presented, unless it should happen to buttress a particular point in the briefs of litigants in antitrust cases. Nor ought one to expect that it would be. Similarly the antitrust laws cannot be expected to provide the entire solution, or even a major portion. The unending fight to preserve as much as feasible of a democratically controlled, free enterprise economy is everybody's job, a continual struggle.

in which every agency of business, labor and government must do its part. Not merely the antitrust laws and agencies but all of us are responsible for failure to "protect and preserve a broadly competitive system."

Edward H. Levi

University of Chicago Law School

I think there are three principal reasons for the relative ineffectiveness of the antitrust laws:

1. The courts are not sufficiently aware of the monopoly problem. As an aspect of this, the courts have not sufficiently considered size rather than the abuse of monopoly position to be the violation of the law. And as another aspect of this, they have tended to think that a finding of violation and an injunction against further monopolistic actions constitute sufficient relief. I believe that this point is the result of points (2) and (3).

2. The Department of Justice has never had a sufficiently sustained and energetic policy of enforcement. Enforcement is sporadic; vigorous enforcement is branded as witch hunting and is followed by a "period of reasonableness." One result of this is that the courts are not forced to face the problems of size in monopoly. Because there are so few monopoly cases, the courts are relatively uninformed as to economic conditions in key industries and the law itself does not develop as rapidly as it would if more cases were brought. Enormous gaps in the law are permitted to remain and this makes it much easier to have an ineffective enforcement policy.

3. Economists in general, I think, must bear a great share of the blame. The general impression of the public is that monopoly is inevitable and since it is inevitable, it is silly to try to prevent it. A variation of this is the popular opinion that it is childish to be against monopoly (perhaps because it is inevitable) and that, therefore, a monopoly cannot be said to be "bad" or a violation. In other words, I think economists have failed to distinguish between descriptions of our present economy and analyses of what can or ought to be done. Thus, even critical essays on the present state of the economy become a basis for a weak enforcement policy and for a lack of understanding on the part of the courts.

Ben W. Lewis

Oberlin College

In my judgment, the antitrust laws have made our economy much more competitive than it would have been in their absence. Furthermore, they can continue indefinitely to be so employed as to preserve a condition of more vigorous competition than we could otherwise hope to enjoy. On the other hand, the conditions of their application have been such as to make them less effective through the years and at present than they might have been. Some

of these conditions can be improved. I have come to believe, however, that the basic purpose we have sought to achieve through the antitrust laws is inherently incapable of accomplishment; that these laws now represent a rear-guard (albeit, a very important rear-guard) action; and that in the years ahead a considerable and increasing portion of our economy will come to be controlled through conscious public action (probably public enterprise) rather than by the "automatic" processes of competition bolstered by the Sherman Law.³

We are capable of doing a better job with the antitrust laws than we have done in the past. Probably they need statutory strengthening along the lines suggested by Messrs. Kefauver and Watkins at the December, 1947 meetings of the American Economic Association (see *Papers and Proceedings* of the Association, May, 1948, pp. 182-202; 204-8;⁴ certainly the Anti-Trust Division needs more funds than Congress has ever yet seen fit to appropriate; and above all else enforcement of the laws stands to gain from any increase in public support, executive drive and judicial understanding that can possibly be developed.

But even if these measures should all be brought about—which I very much hope and very much doubt will be the case—it is my belief that the antitrust laws are inherently incapable of maintaining really effective competition. The *real* difficulty—the *basic* difficulty—in their application and enforcement is not to be corrected by statutes, appropriations or sentiment, sympathy and eagerness. It is simply not to be corrected—period.

The Sherman Act was put on the books in 1890; in 1948 we haven't the foggiest notion of the meaning of the Sherman Law as it relates to the prime organizational problem that has confronted our economy throughout the full life of the law—large-scale corporate industry. We are still playing guessing games with the Supreme Court. But, while it is easy to lay the blame at the door of the Supreme Court, I will suggest that if the Court has failed at any time to express accurately the intent of Congress, it has always been within the formal competence of Congress to change the law in line with its desires. But Congress has had no precise mandate or direction from the American public; and the public, in turn, has been given nothing but the most confusing advice from its technical experts—its professional economists. It's a tough problem—inherently tough—and just possibly the real reason why the interpretation and application of the Sherman Law is still muddled and uncertain (and is likely to remain in that state) lies in this fact.

It is my belief that "free enterprise," as an economic system, is breaking up. The most we can expect from the antitrust laws is that they will make the break-up and the transition easier to bear. I want better laws, better enforced; but no revision of the laws, no additional appropriations, and no hypo-shots of zeal in enforcement will be capable, in my judgment, of bolstering competition

³ It may be, of course, that factors and forces other than the failure of the antitrust laws will operate more powerfully and immediately to produce this result.

⁴ I participated in the discussion in question, and with the permission of the secretary of the Association use some of the material which I presented and which appears in the *Am. Econ. Rev., Papers and Proceedings*, Vol. XXXVIII, No. 2 (May, 1948), pp. 211-14.

sufficiently to warrant permanent reliance upon it as the central organizing and regulating force in our economic system. The way is effectively and permanently barred by the presence—the increasing presence—of large-scale industrial, marketing and labor units. We will not reduce their scale in any significant measure.

I do not argue that competition is absent from our economy; it is present and at times it may break out fiercely in the most unexpected places. But it occurs systematically and regularly only in a narrowing area; elsewhere it appears only spasmodically, when someone feels that, as a matter of policy or strategy, a spot of competition would be worth trying. This I believe will continue inevitably to be the case, conspicuously, in the basic, mass-production industries. It is quite true that many people and many firms are engaged in competitive activities, but the kind and extent of their competitive maneuvers are determined by the management of powerful industrial units who are largely free to indulge in as much or as little competition as they see fit. It is "cold competition," a game, without compulsions either in the event or in timing. Anti-Trust can annoy, but it cannot compel a systematic course of competitive conduct. Competition today is sporadic in its operation and unpredictable in its effects. It simply is not present in a form and degree that will justify continuing confidence in its capacity to perform the highly important duties which the logic of free enterprise requires it to discharge.

Competition has not been supplanted by complete monopolies engaged in spectacularly evil conduct; what we face is the quite undramatic development of conditions, short of monopoly, under which competition as a regulatory force is being rendered ineffective. Important economic decisions are not ground out by impersonal competitive exchange in an open and driving market; they are made quite personally, by men—relatively few men—whom we do not choose and over whom we have only the most tenuous controls. "Free enterprise" as we know it, and as we shall continue to know it until we harness it by forces stronger than any competition we can conjure up and sustain, is *really free!*⁵

Granted that many present-day corporations and corporate empires have been expanded beyond any point that can be defended on grounds of pro-

⁵ The exact extent and degree of competition obtaining at any time in any industry, and the exact point at which competition in particular situations, or generally, becomes ineffective, are not matters of precise factual measurement. Answers here must be in the nature of value judgments. Obviously, these judgments do not occur in an atmosphere barren of facts. Facts bearing on the nature, causes and extent of industrial concentration (intra- and inter-firm), the determinants and limits of managerial policy decisions, the nature of business and financial practices and arrangements, the nature and effects of public policies—all of these contribute to the complex out of which the value judgment emerges.

In my own case, for instance, I am moved by the kinds of industrial, financial and marketing situations and arrangements analyzed in such studies as T.N.E.C. Monograph No. 21, those set forth over the years in Anti-Trust and F.T.C. proceedings, and those familiar to all of us who had an opportunity in connection with our N.R.A. and O.P.A. duties to review industrial policies and practices. None of this impresses me as "sensational," nor does any of it seem to me to "demand" immediate drastic public action; none the less, for me, it adds up to the convictions expressed in this paper. I am very much aware, however, that these convictions are value judgments.

ductive efficiency, I still believe that they cannot be reduced and broken up sufficiently to insure effective competition without exacting a greater price than we shall be willing to pay. The scale of industrial and marketing operations required to support us in the style to which we have (or should) become accustomed is still so large as to render the resulting "competition" quite undependable as the regulator of our economy. I can easily believe that technological developments now foreseeable by those with vision may in some industries make possible the attainment of optimum productive efficiency at scales of operation less extended than those currently thought necessary.⁶ I hope they do. When it happens, I'll believe it. Until it happens, however, I am not willing to alter either my predictions or the policy conclusions which those predictions seem to me to establish. The scaling down of hitherto large-scale industry may come about in certain instances as the natural result of technological innovations, but the movement has certainly not yet begun in strength, and we would be quite ill-advised to force such a break-up indiscriminately across the industrial front by starry-eyed governmental action taken in anticipation of innovations which as yet are only guesses.

Recently it has been sought to inject realism into inquiries concerning the effectiveness of the antitrust laws by directing attention to the concept of "workable" competition. Competition in the actual world is recognized as being less perfect and precise in its operation than the unrealistic, classical, class-room concept of "pure" competition, but it is thought, nonetheless, to be doing quite capably the promotive and regulatory job which under the logic of "free enterprise" it is supposed to do. It works! The exact bounds and content of workable competition have not been authoritatively determined and defined, but it is suggested that competition is probably present and "working" in an economy such as ours which is characterized generally by progressive technology reflected in lowering prices, increasing output and new and improved products. The point is made that in appraising the effectiveness of competition we should not look to form and structure (the number and size of firms in the several markets, *i.e.*, the degree of "concentration"), but, rather, to market results. If prices, and the kind, quantity and quality of products are satisfactory, then competition is satisfactory; it is working. The conclusion seems to be that competition is "working" throughout most of our economy.

I am willing to accept considerable leeway and tolerance in the operation of competition (or any other regulatory force, for that matter), but I am not willing to judge its effectiveness or to decide whether or not it is workable and working solely or even largely on the basis of "results." Prices have been lowered, output is large, and there have been innovation and improve-

⁶ See G. M. Blair, "Technology and Size," *Am. Econ. Rev., Papers and Proceedings*, May, 1948, pp. 121-52.

⁷ E. S. Mason talks of workable competition in his contribution to this symposium and in his paper, "Competition, Price Policy and High Level Stability," at pp. 19-31 of *Pricing Problems and the Stabilization of Prosperity* (1947) published by the United States Chamber of Commerce. See, also, J. M. Clark, "Toward a Concept of Workable Competition," at pp. 452-76 of *Readings in the Social Control of Industry* (Blakiston, 1942).

ment in techniques and goods. But, unfortunately, these results do not tell the story. Results alone, throw no light on the really significant question: have these results been *compelled* by the system—by *competition*—or do they represent simply the dispensations of managements which, with a wide latitude of policy choices at their disposal, happened for the moment to be benevolent or “smart”? This points up the real issue. The answer is of the very greatest moment for the future of our economy, and in seeking the answer the matter of form and structure (the degree of industrial concentration) is of foremost importance.

I will concede quite readily that we may enjoy immediately satisfactory prices and output even though competition is not perfect; indeed, I will go further. We may enjoy immediately satisfactory results even though competition is not “working,” if the persons who make decisions are willing, in their wisdom or benevolence, to permit such results to trickle down. The absence of identifiable extortion or restriction does not, by itself, establish the presence of effective competition. For competition to be effective or workable, or even acceptable, in any significant, lasting sense, it must not only permit, *it must compel the results we want by the necessary and continuing operation of its processes*. The array of price and output policies from which managements are free to choose must be strictly limited. Satisfactory results which happen but which, equally, might not have happened are not good evidence of the successful working of an economic system or of competition as an integral part of an economic system. The *process* by which results are achieved and assured is the very essence of an economic *system*. As a consumer I like low prices, but to me competition is not “working” in an industry whose individual firms are powerful enough to hold prices down in the face of a general inflation. The immediate result is welcome, but I want the decision on prices to be made by society—either through the compelling forces of a competitive market or, if competition is not sufficiently workable to compel the decision (or the decision we want), then by action of a responsible government.

The key to the effectiveness of competition is to be found in its power systematically and predictably to compel economic decisions, and I do not believe that any such power or force characterizes the competition present in industries composed of, or dominated by, either a single firm or a few large firms. Such firms have the power to select their price and output policies from a wide range of possible action; neither competition nor any other force or combination of forces restrains or compels their choices except, at best, at the outermost limits. They are possessed, as well, of power to increase their defences against competition and to protect their positions. To speak of *potential* competition as a compelling regulatory force in this situation is to be blind to the strength of the factors that retard and will continue to retard the drive of potential competition to become actual competition.

Some indication of the looseness of the regulatory force of competition in mass production industry is to be found in the exhortations increasingly being delivered by economists, public officials and “enlightened” business leaders, urging managements to shape their price, output, wage and invest-

ment policies in accordance with long-run, over-all social considerations: increased purchasing power and consumption, full employment, an economy of plenty, etc. If competition, actual or potential, were really effective, these exhortations would be quite uncalled for and wholly useless. Need I add that as a prime regulatory instrument in our economy exhortations would seem to leave much to be desired? Something more certain in its promise and compelling in its force than an appeal to the good will and social consciousness of business leaders is called for in economic situations where sound criteria of individual and corporate gain run directly counter to sound criteria of general economic welfare.

Although the present discussion relates primarily to antitrust and industry, it is pertinent to note that developments corresponding to those in industry are under way in labor and agriculture. None of these is likely to be reversed. It could be, of course, that these groups will come to serve as checks upon each other, and that our economy in its movement away from dependence upon individual self-interest and competition will sometime emerge as a society of "responsible men" balanced in "responsible groups."⁸ I note still another major development, however—big government—and my own *guess* is that we shall come increasingly to rely upon government (*i.e.*, upon ourselves in our collective *governmental* rather than our *economic group* capacity) to perform the economic tasks hitherto assigned to competition. Nor am I particularly disturbed by this; personally, I am not fearful of the democratic process and I do not doubt its ability to maintain its democratic character.

A final point, involving a different meaning for the term "workable": is competition any less "effective" than it needs to be in order to be "workable"? The suggestion implicit in this question is that pure and perfect competition is unsuited to the physical and economic requirements of modern mass industry with its specialized capital—that managements of these firms need great leeway, need freedom from the unreasonable, nagging restraints and dictates of the kind of competition appropriate to more primitive markets. This I can believe, but it seems to me to constitute not only a convincing explanation (and excuse) for the looseness of competition, but also a confirmation of the fact of its looseness—such looseness is inherent and inevitable! The fact that managerial action must be free (and, hence, *ought* to be free) from the frustrating hand of competition means simply that under modern conditions of production and marketing the kind of competition that will work so far as individual firms are concerned is quite unworkable as the prime regulatory instrument for the economy as a whole. The freedom of action needed by modern management, if its search for individual security is to succeed, is so great that whether because we fear its misuse or because we value our self-respect, we cannot properly leave it, unrestrained, in private hands.

What we want in a democratic economy are compelling forces that will drive individual activity systematically and predictably within narrow channels named and approved by society. Social responsibility must attach to

⁸ See J. M. Clark, *Alternative to Serfdom* (Knopf, 1948).

individual economic decisions: economic decisions must be made under such conditions that lines of responsibility and control run from those materially affected by the decisions to the persons engaged in making them. Under the classical logic of free enterprise social responsibility was assured by the presence of competition; under modern conditions of mass production competition cannot, and cannot be made to, give us the assurance we need.

Let me make my indictment quite clear: I am not undertaking a shotgun attack on all of the inequities and shortcomings of our present way of economic life. Neither am I suggesting that our present way of life doesn't furnish quite a lot of us with quite a lot of relatively secure comforts. Indeed, it is part of my thesis that the economic ease which we are currently permitted to enjoy serves to insulate us from any considerable awareness of the loosening processes at work within our economy. My charge relates to the dilution and weakening of competition as a compelling regulatory force, and the consequent growth of irresponsibility in the making of economic decisions; and to the disintegration of free enterprise as a system which this development reflects. Irresponsibility as an abiding feature of an economic system is not made palatable by the fact that the power it represents is not always misused, and disintegration is no less real because it is cushioned and draped.

We need the antitrust laws, refurbished and refueled. But we shall need more—a lot more.

Irving Lipkowitz

Reynolds Metals Company, New York City

The antitrust laws are at best a negative means of promoting competition. Their province is limited to the violations of law. As a consequence, they can deal only with the wrong-doer, and only in so far as the wrong is recognized by law and satisfactory evidence against the culprit can be obtained by the law enforcement agency and presented to an appropriate court. Law enforcement by itself, no matter how broad and competent, can no more do the whole job of establishing and maintaining a competitive system than it can produce harmonious relations between labor and management.

Half a century ago, when the basic pattern of the antitrust laws was fixed, it might have been enough for government to be merely antimonopoly. Perhaps in those days the government would have had merely to eliminate the specific abuses of monopoly power in order to give competition a fair chance to develop and thrive in most industries. Whatever the situation was then, today much more than that is needed if there is to be real competition in most of the key industries. Many of the obstacles to unrestrained competition are "legal," and therefore beyond the reach of the government's antimonopoly laws and agencies.

Healthy and productive competition is a way of business life, not merely the absence of illegal monopolies. Like democracy, it must be cultivated. It does not come naturally to all businessmen and does not survive or maintain

itself with equal ease in all industries. If our economic system is to be more effectively competitive than it is now, the government will have to promote such competition by more direct and positive means than mere law enforcement.

A government agency, sufficiently endowed with authority and appropriations to attract competent personnel, should be created to promote competition. It should not be the traditional "small business" clique. All big business is not automatically monopolistic, all small business is not necessarily competitive. This procompetitive government agency would not have the responsibility for enforcing the antitrust laws. That would still be the function of the present antimonopoly agencies. However, like any other government agency, it would refer to the Department of Justice any violations of law which incidentally come to its attention.

The first task of this agency would be to find out what is the state of competition, and conversely of monopoly, in each of the important industries. Where it found that competition was weak, it would then have to decide how desirable it would be to stimulate or promote greater competition in that industry. If the decision were in favor of stimulating competition, then a thorough diagnosis would have to be made to determine the best course of action. In one case the problem might be financing, in another patent or technological pools, and in the third case the advantages which the dominant company might get from a highly effective intensive advertising campaign. In some cases this agency might find the government can do nothing to establish competition in an industry unless it is willing to subsidize some of the "competitors" ad infinitum.

At each stage in its analysis the procompetition agency should make its findings and recommendations public and understandable. If nothing else, this agency would tell the country how much or how little competition there is, in what industries, and what—if anything—could be done to improve the situation.

This agency should be left free to recommend any course of action which it deemed most practical for the particular situation. In one case it might require no more than internal rearrangements within the industry without any further government intervention. At other times this agency might find it necessary to seek special government financing for the less powerful members of an industry. Or, its program might be so drastic and the industry so important as to require Congressional review and approval. Under no circumstances should the procompetition agency be required to limit its remedies to just those which could be handled through court procedures or consent decrees.

Will such an agency be so powerful as to jeopardize free enterprise and democratic processes? No, because its power will vary from industry to industry, directly with the strength of monopoly and inversely to the degree of competition. Its decisions should be subject to review by a board of competent representative citizens which should pass on any challenged facts and on any charges that a particular recommended remedy is too harsh. How far

such an agency would be permitted to go in a particular industry would depend on how anxious the nation was to have that industry more competitive.

There are probably many different ways of achieving what the procompetition agency outlined above is intended to do. But in any case the approach must be that direct and positive. The difference between promoting competition and antitrust law enforcement is the difference between a Tennessee Valley Authority directly stimulating the greater use of electricity and a state regulatory body trying to do the same through rate-making procedures. The government should concentrate its efforts on getting an industry to do the right things more often and not confine its efforts to restraining or punishing the wrongdoers.

If the traditional antimonopoly approach is to prevail, however, then the antitrust agencies should have as broad powers and extensive facilities for watching and intercepting the flow of commerce as police departments have with respect to the flow of vehicular traffic. Lacking such powers, these agencies should not be held responsible for the defective flow of commerce.

The powers of the antitrust agencies to get essential facts about conditions in a particular industry should not be limited to the subpoena rights of a litigant. Every investigation does not presuppose a lawsuit. Moreover, the standards of proof in a monopoly case should not be the same as when a human defendant's life is at stake. In actual practice, the more powerful the monopoly, the more difficult it is to get the evidence necessary to convict it. The more dominant a monopoly is, the more reluctant businessmen are to testify against it—for fear of repercussions. An all-powerful monopoly rarely finds it necessary to lay down the law, orally or in writing, to its would-be competitors. The anomalous result is that the more evident the monopoly, the less evidence the government can obtain. Only when the monopoly lacks full control does it have to threaten and take the kind of actions which are the makings of a successful antitrust action.

The courtroom processing of antitrust cases can also be improved greatly. Specialized courts are needed, staffed with a judiciary well versed in the complexities and realities of business practice. Such judges would then be in a position to adapt the rules of evidence to accelerate the presentation of business facts without sacrificing the quality of proof.

Essentially the lack of adequate governmental machinery for guaranteeing the nation a competitive economic system reflects the indifference or hostility of both organized business and organized labor. Of course, within each industry both groups want to get the benefits of competition in other industries, but do not want to give others the benefit of competition in their own industry. Any program for making our economic system more competitive must therefore start with a campaign to get industry and labor groups to support actively specific proposals to promote competition and to make anti-monopoly drives more effective.

Edward S. Mason

Harvard University

The great difficulty in answering the question you raise lies in the interpretation one is to put on the phrase "broadly competitive economic system." There are at least two sources of confusion: (1) is competition to be understood strictly in the market sense of the term or does it also embrace considerations having to do with the structure of the *political* economy, *i.e.*, concentration of economic control?; and (2) in so far as attention is concentrated on competition in the market sense, how does one measure departures from competition, *i.e.*, the degree of monopoly.

1. When people speak of a decline of competition, they frequently are thinking of such phenomena as the rise of the large corporation and the relative decline in the importance of sectors of the economy associated with small scale enterprise, *e.g.*, agriculture, which may or may not have anything to do with competition in the market sense of the term. One way of characterizing the phenomena they have in mind is "concentration of economic control."

There are various ways concentration may be measured, each of which has its own significance. Among them is a number of employees per business unit. It is, of course, obvious that the ratio between the number of business units and number of employees is continually declining as a result of the continued shift from agricultural to industrial employment, the relatively rapid growth of sectors of industry characterized by large-scale enterprise, and the increase in the size of the optimum unit in almost all branches of industry.

There is, furthermore, little doubt that this changing ratio of number of firms to number of employees has great significance for the functioning of the *political* economy. It affects the location of political power, the character and size of pressure groups, employer-employee relationships, etc. It is certainly true that it is changing the character of American democracy and it may be true that it threatens the continued existence of democratic institutions.

But it has no necessary or even obvious connection with competition in the market sense of the term. No one has been able to show as yet that monopoly is more important in the economy than it was fifty or one hundred years ago or that competition has declined. Partly this has to do with ambiguities in the interpretation of competition and in difficulties connected with the measurement of departures from competition in whatever sense the term is used.

2. The most precise notion of competition is pure or atomistic competition but this is (a) a limiting concept in (b) a purely static analysis. Although it is possible to measure *conceptually* departures from pure competition in various ways such as ratio of price to marginal cost, ratio of actual to competitive profits, ratio of actual to competitive output, etc., each of these conceptual measures is firstly only a partial measure even on its own terms and assuming static conditions, and secondly, is not susceptible to statistical application.

Moreover, this whole conception of competition and monopoly is purely static. In the American economy new products, new techniques, new locations, changing consumer tastes, etc., are continually breaking the existing patterns of market relationships and forming new ones which in turn emerge only to be broken. How is this process to be fitted into conceptions of monopoly and competition? No one has as yet provided any satisfactory answer.

In default of answers running in terms of the degree or extent of departure from pure competition people have recently sought an answer to the question whether various industries are or are not "workably competitive." Presumably this notion fastens attention on the *results* of a particular market structure. Is the existing set-up accompanied by a progressive technology, the passing on to consumers of the results of this progressiveness in the form of lower prices, larger output, improved products, etc.? Although there is a certain attractiveness to this conception, it must be admitted that no one as yet has given it any precision. Whether a given industry is judged to be workably competitive will depend to a very substantial extent on the "ideology" of the judges. And who is to say in these terms whether the American economy is or is not more "broadly competitive" now than it was in 1890?

Whatever answer is given to this question, I believe myself that the American economy is in fact substantially more "workably competitive" than it would have been without the existence of the antitrust acts. This is due, I believe, not so much to the contribution that particular judgments have made to the restoring of competition as it is to the fact that the consideration of whether a particular course of business action may or may not be in violation of the antitrust acts is a persistent factor affecting business judgment, at least in large firms.

It is frequently stated that the greatest defects of antitrust policy are in handling the monopolistic or monopsonistic bargaining power of the large firm and the problem of mutual interdependence which may exist when a few large firms are predominant in a market. This judgment, however, usually will be found to emanate from those who have a static approach to the problem of monopoly and competition. Until it is clearer to me than it is now (a) that the large firm in the presence of manifestly dynamic influences exerts an adverse monopolistic influence on the functioning of the economy and (b) that any possible action under existing (or a modified) antitrust policy would remedy the situation, I have my fingers crossed.

Breck P. McAllister

Donovan, Leisure, Newton, Lumbard and Irvine, New York City

I would group my impressions as to the effectiveness of the antitrust laws into two quite separate and distinct categories.

First, I think of effectiveness in terms of a police agency prepared to deal with ordinary police functions. In this category I include such important matters as price-fixing at any level of trade, and what often goes with that,

efforts by trade groups to fix and maintain particular channels of distribution. On this last point I have in mind efforts such as those of a wholesale group to prevent manufacturers cutting them off by selling direct to retailers, efforts by a retail group to prevent manufacturers from selling direct to consumers, and combined efforts of both kinds of groups to the same end. In short, I have in mind any effort at cartelization or stratification of the distributive channels. In this category you find not only efforts of these groups to maintain their status but also efforts directed towards price control.

As to the general effectiveness of antitrust as a police force in this important category of cases where there are no questions of uncertainty as to the law and the criminal process is generally used, it is my impression that on the whole we have, to a considerable extent, prevented our economy from crystallizing after the manner of, let us say, the British economy. We have not, however, been entirely successful. One failure grows out of the successful effort of the trade groups in question in our legislative halls, both federal and state. In this connection I have in mind particularly the so-called "fair trade laws" and "unfair practice acts" in the state legislatures, together with the Miller-Tydings Amendment to the Sherman Act. In short, we have an important degree of disagreement as to the direction which our public policy should take.

The efforts of Anti-Trust have also been hampered in varying degrees throughout the years through lack of adequate appropriations and personnel. The remedy here is plain and I should like to see it applied by the Congress. I know of no reason why, if adequately equipped, Anti-Trust could not be an effective instrumentality to maintain an adequate play in the joints of our economy in the area I have indicated. In fact, it seems to me that over the years much has been accomplished, and as we look at our economy and contrast it, again with the British, we find that the distributive trades are in a position that I, for one, would describe as a broadly competitive system.

You will notice that in this category my emphasis has been upon the distributive trades but I include in this category manufacturers in so far as their activities are directed to the ends I have indicated.

My second category is a category of a quite different sort. Here I am thinking in terms of the effectiveness of our antitrust laws in checking bigness. We have bigness and lots of it in many important industries. If I detected in your letter the assumption that one of the objectives of the Sherman Act was to make small business out of big business and keep business small, I would question this assumption. Put in another way, I do not think it was the objective of the Sherman Act to keep small business small. Throughout our economic history since 1890 we have had lots of small businesses that have become big. Henry Ford is an example that comes to my mind quickly. Many more exist in our important industries, new and old. Looking at this same problem from another point of view, you come to the question, how big may these enterprises be allowed to become before

they transgress some rather ill-defined notion of public policy? Any effort to answer this question will, of course, bring up a large set of questions with which I am not competent to deal.

It seems to me that your inquiry suggests that in some way Anti-Trust has been ineffective in keeping small business small or, put in another way, keeping big business from getting too big. In this category the problem that confronts Anti-Trust is tremendous and it should not be surprising that we find ourselves with big business in many important industries. I do not want to attempt to state in a few short sentences why business is big. That is a study in itself and it is a study that must take account of important technological and economic factors. Would we have better and cheaper automobiles if we had 100 little businesses making them? A question such as this might be asked as to a great many industries and the only meaningful answer would be one that came from a careful study of that particular industry. The answers might be quite different in different industries.

Another important aspect of the problems in this second category is the question of the effect of bigness on price and other competition. I dare say the economists are having great difficulty in analyzing the important effects of bigness on the traditional economic thinking as to supply, demand and price and the many other important manifestations of competition. I can only give you the impression that I have from close observation of the behavior of a few industries and the effect of the enforcement of our antitrust laws. It is my impression that today, more than ever before, our business leaders are aware of Anti-Trust and take account of public policy as it crystallizes from time to time in Anti-Trust and the decisions of the courts. The days of the ruthless business leader are over—and have been for some years.

I also think that it is too simple an assumption to make that because there may be only four or five companies in a given industry that, therefore, price agreements and other activities of that sort are in full swing. Bigness has its problems and plenty of them and it has important responsibilities in its industry. I am in no position to say, from the point of view of the consumer, that we would have better goods at lower prices if we had more and smaller companies in a particular industry. From the point of view of the labor leader, it is quite possible that in some industries only bigness will make it possible to have an adequate wage and a lower price to consumers. In another industry smallness as against bigness may be irrelevant. The answers to these questions might be "yes" in one industry and "no" in another and both answers would have a lot of guesswork in them. Our public policy is ill-defined. Our thinking, too often, is in terms of what to do about bigness rather than in terms of the objective of our impressive economy.

Harlan L. McCracken

Louisiana State University

If one were to ask me why our antitrust laws and enforcement had been of almost no avail, I would say that it is due primarily to the "Fourth Division of Government," namely lobbies and pressure groups. Every combination which desires to restrain trade constitutes a terrific pressure group. Witness the silver bloc, the farm bloc, the real estate lobby and the ever-present pressure from steel and aluminum.

This is the real and basic problem. All pressure groups desire benefits and special privileges for themselves, regardless of their general effects upon the national economy. Also, they are shortsighted and seem always to be working for a temporary *boom* even if it is pretty clear that the long-run results will be a *bust*.

Some have thought that we will have to organize a "consumer pressure group," seeing to it that it has a very large membership, a good treasury, and strong officers so that every time a small bloc presses for class legislation this large consumer group can force legislators to work at the issue from the national point of view and from the population as a whole. Without such an organization with officers and a treasury the case against blocs and pressure groups usually always goes by default.

From the economic standpoint I see no fundamental reason why we cannot restore a reasonable and high degree of competition if we want to. For example, we know there is a powerful connection between protective tariffs and trusts. Yet tariffs are man-made and can be unmade by man. There is no economic or logical defense for trying to strengthen an industry like steel or aluminum by giving it a protective tariff and then trying to weaken it by antitrust prosecution. I would, therefore, propose that wherever we find combinations restraining trade against the public interest we examine the tariff; and if they have been made immune to foreign competition by a tariff and immune to domestic competition by a trust, then I would say that the first step should be a sufficient reduction in the tariff to force foreign competition. Of course if it be an international cartel, then we would need to take direct legal action.

The difficulties of restoring a high degree of competition are almost wholly political and not economic or legal. Antitrust laws can be enforced where there is sufficient *will* to enforce them, and competitive enterprise can be made to succeed if given the proper opportunity and environment.

George Nebolsine

Cahill, Gordon, Zachry & Reindel, New York City

Your letter raises a question of considerable importance today—as to whether the Sherman Act, enacted prior to development of mass-production techniques, the invention of the automobile, the radio, synthetic chemicals

and the development of atomic energy, and reflecting the philosophy of the mid-19th century economists, has served to preserve a competitive system. I shall express my views briefly and ask you a question in turn.

Certainly, the conception of competition has been modified in respect to public utilities, carriers, and a host of economic endeavors which have come under government regulation. It is the current thesis of some economists that the alternative to the widest kind of competition—indeed, of atomization of industry—is government regulation of industry generally. I cannot concur in this view, since with a few (and very deplorable) exceptions nothing approaching the pure competition of atomized economic units as laid down by 19th century economic thinking has ever existed in industry. On the contrary, there has evolved, through trial and error and under the Sherman Act, a very great industrial expansion, the competitive behavior of which squares neither with the theories as to pure competition nor with the theories of monopoly behavior. There has taken place in industry generally in the last forty years amazing progress—through innovation, improved quality of product and of services rendered in connection therewith. Except for postwar distortions, there has been a general decline in prices of many manufactured articles. Labor conditions have improved.

There have been times in almost all industries when increase in unit size has been essential for efficiency and when cooperation among industry members at technical, marketing and financial levels has been essential to progress. Much of the concentration or cooperative endeavor that has taken place in response to economic needs has resulted in advancing the public interest.

As I read Dr. E. G. Nourse and Dr. Leon Keyserling, and other contemporary economic authorities, I find that an important trend of economic thinking points in the direction of making over-all economic *performance*, rather than *structure* of enterprises the main—if not the decisive—test of the public interest as applied to industry.

Such a view of the situation does not lead to the repudiation of the principles of a free market or the repeal of antimonopoly laws or the encouragement of monopolistic practices; it does suggest a more realistic view of the varied problems of industry than could be gained from thinking about competition in the abstract and by finespun interpretations of the three lines of Section 1 of the Sherman Act.

There is a suggestion in your question that the antitrust laws have been *ineffective*. I disagree with this: I believe they have been very effective. The economic structure of the United States, though far more advanced technologically than that of other countries, has greater potentialities of intra- and inter-industry competition within it than foreign industry structures which escaped the influence of the antitrust laws. Our competitive structure is an asset in our economy and we should preserve it wherever it can subsist. But we should not expect the *form* and *structure* of industry to reflect primitive technology. We should not seek to artificially create multiplicity of units through atomization of industry without regard to technological and market requirements. This would be a retrogressive step, out of keeping with economic needs.

The Supreme Court in the recent case *U.S. v. National Lead* refused to divide up the two companies engaged in the industry. The court invoked the tests of necessity, practicability and fairness of divestiture of plants. It stated that there was no showing that four major competing units would be preferable to two, or that six would be better than four.

The question posed by the Court is a challenge to the advocates of atomizing industry. Is it demonstrable that four competitors are preferable to two? Does it make any difference to the answer if the two are equally advanced technologically and are well-capitalized concerns that have enlarged their plant and improved the product? What if the alternative is a "sick" industry composed of competitors that can barely get along and are not in a position to introduce revolutionary improvements in the manufacturing process or to establish a product of high reputation in the market? In other words, is the test of the public interest performance or form? I do not think we can have it both ways.*

* I replied to Mr. Nebolsine's questions as follows:

You asked me for my opinion as to whether or not four sets of competitors are preferable to two, under various sets of circumstances which you state. I am glad to give you the best answer I can to that difficult question. My answer is that, in the interest of maintaining a broadly competitive system, there is a presumption in favor of having four rather than two competitors, and six rather than four.

As I see it, this presumption should be upset only when there is an affirmative showing that continuation of the larger number of competitors is resulting in failures such as those to capitalize fully the advantages of large-scale production or, as you suggest, is resulting in a "sick" industry composed of ill-balanced competitors, incapable of introducing revolutionary improvements in the manufacturing process or establishing a product of high reputation in the market.

I am not altogether sure that the desirability of having a broader competitive base would not justify foregoing full exploitation of the advantages of large-scale production. This, I take it, was the position taken by the National Association of Retail Grocers at their recent convention when, by inference, they favored the elimination of quantity discounts to "a small number of giant corporations" even though they could be justified in terms of the saving affected by handling the large quantities involved. In terms of maintaining a safe base of political democracy, which is my central interest in the antitrust laws, I can envisage some advantages in such a policy but I do not now embrace it. However, I do think it is demonstrable that four competitors are better than two unless having the smaller number clearly results in technological and economic gains of the sort you mentioned.

When there are two competitors rather than four, the chances of collusion about prices and production are obviously much increased. While I think too much emphasis is generally placed upon the conspiratorial impulses of the business community, I do not think these chances should be ignored. Likewise, in the complete absence of any collusion, the chances that a monopolistic course will be taken in the "follow the leader" pattern are increased when there are only two competitors.

If the heads of the two surviving firms were the hard-driving, fiercely independent type of businessman who has played such a large part in the industrial development of the U.S.A., two of them would be enough to create a ruggedly competitive situation. But if the two were of the genteel, clubby and inclined-to-take-it-easy type which is also known in the high reaches of American business, two companies might get together and tend to sleep together indefinitely. When the number of firms involved is small, the chances of having the industry animated by vigorously competitive leadership also seem to me to be relatively small.

Beyond those which I have mentioned there are, I believe, many other advantages in

George W. Stocking

Vanderbilt University

I believe the chief reason the antitrust laws have not been more successful is that no politically powerful economic group wants them to be generally enforced. This is partly due to ignorance and partly to vested interests. But regardless of the reasons neither big business, nor labor, nor the farmers believe in a free-enterprise system. A paraphrase of Pope expresses the trend in public attitudes.

Monopoly is a monster of such frightful mien

That to be hated needs but to be seen (Sherman Law 1890)

But seen too oft, familiar with her face

We first endure (Rule of Reason 1911; *U.S. v. U.S. Steel Corporation*, 1920), then pity (Federal Trade Commission trade practice conferences and codes; trade association activities, etc.), then embrace (NRA).

Big Business has failed to distinguish between free enterprise and private enterprise and apparently is unwilling to admit that the former is essential to the preservation of the latter. Whether this is due to ignorance or hypocrisy does not affect business' stubborn insistence that it must be left alone. The most recent illustration is the National Association of Manufacturers' characterization of the Federal Trade Commission's recommendation for amending Section 7 and 11 of the Clayton Act as a witch hunt.

Labor professes to oppose business monopolies, but shouts to high heaven against any proposal to curb its own monopoly power.

Farmers have become so used to subsidies for output restriction and destruction that they regard them as constitutional rights.

Under these circumstances not the failure of antitrust but the basic vigor of competition is amazing. Between 1911 and 1930 the oil industry's monopoly had been transformed into competition so ruinous that the states stepped in to forbid it. Between 1897 when the Supreme Court came to the rescue of the sugar trust (*E. C. Knight case*) and the late 'twenties sugar refining had become highly competitive—American control having declined from 97 per cent to about 40 per cent—and the industry was "demoralized" by "ruinous" competition.

Bear in mind that the technique of competitive readjustment is ruin and bankruptcy, but among modern social groups nobody wants to be the sacrificial lamb even for the good of the tribe.

If we really wanted a competitive economy it would be necessary to:

1. Revise our patent laws so as to give venture capital easier access to modern technology.

having more rather than fewer competitors. I trust, however, that I have successfully argued that the strong case for having four rather than two competitors can only be upset by a clear showing that the lesser number is absolutely essential to realize the advantages of mass production, or to overcome otherwise inescapable economic weakness. It is my impression that the showing in question is more often assumed than made.—D. M. K.

2. Prohibit mergers so as to make business firms as small and numerous as is consistent with the economies of mass production.

3. Require federal incorporation for firms the assets of which exceed a specified minimum and which do business in interstate commerce, and limit the use of the holding corporation.

4. Supply more adequate funds for the enforcement of antitrust. Eternal vigilance is the price of liberty.

5. Curb labor monopolies. Specifically, prohibit industry-wide bargaining. The ideal unit of bargaining would probably be the firm and the size of the firm would be limited in accordance with the principle set forth under (2) above.

6. Lower tariffs.

7. Through monetary and fiscal policies, stabilize the general price structure; but leave individual prices to seek competitive levels and perform their proper function of allocating resources and distributing income.

8. Curb monopolies of prestige created by advertising where the main effect is to increase costs by diverting customers from one product to a substantially similar product. This might involve limiting or taxing advertising expenditures, government grading to prevent misleading advertising, or service by a Bureau of Standards like that of Consumers' Research.

In brief, it would be necessary to create an environment conducive to the operation of a free economy. If we could solve the problem of industrial stability, *i.e.*, insure an expanding economy, the readjustments in use of resources which competition would require would be relatively painless.

This obviously is a big order and while the broad goal is generally attractive—a maximization of economic freedom, a high level of employment and income, and economical use of productive agents—its specific objectives encounter serious obstacles on every hand.

Myron W. Watkins

New York City

Viewed from the standpoint of the goal at which the antitrust laws aimed (the past tense is deliberate; it's difficult to say what they aim at now, particularly after the Miller-Tydings amendment!), the accomplishment has been meager, I agree. But if one were to speculate on where we would have come out without antitrust, he could hardly conclude that the results have been negligible. Even more industries under the thumb of big business, even more gigantic mergers than those we know, and an even tighter web of collusive restrictions than enmeshes us, these would be our lot. A quarter of a loaf is better than none; but it's not as good as half a loaf!

The explanation of the shortcomings of antitrust, however big or little one regards them, is complex and the ranking of the factors depends on the way one frames the problem. Some people might be content with an explanation that ran mainly in terms of public apathy. Others might find the chief

cause in business obtuseness, callousness, or cupidity. Still others would probably put the principal emphasis on technological "resistance."

For myself, a more significant explanation would be one that took each of these factors as a datum, simply phases of the assumed conditions that serve as a point of departure for the inquiry. Given *some* public indifference, given *some* business obstinacy and trickiness, given *some* technological obstacles, why has antitrust been less effective than it might have been? So framing the issue, the courts, the Congress, and the executive all have a good deal to answer for; and considering the possibilities of independent, constructive action I would distribute responsibility in about that order. In a whole string of cases from the Knight fiasco through Oil and Tobacco, American Can, Shoe Machinery, Steel, Harvester, Swift, International Shoe, to Alcoa, either a different judgment or a different decree might have shaped a different structure for American industry. The significance of Knight, Steel, and International Shoe, for example, reached far beyond the position of the immediate defendants.

Moreover, if judicial interpretation and application of the antitrust laws had been bolder and more clear-sighted, I have a strong feeling that Congress would have been less lethargic. A more constructive judicial record would, I believe, have encouraged Congress to push forward (as it did feebly in 1914 after the *outward* "success" of 1911) on the path of supplementation of antitrust policy. Such a development was indispensable, if antitrust were to become something more than folklore. Patent law, trade mark law, fiscal law, corporation law, in these and other fields, but pre-eminently in these fields, Congress has done nothing, where it might have done much, to bolster antitrust. Indeed, it is hardly too much to say that in each of the fields mentioned Congressional inaction—failure to support antitrust—has been tantamount to sabotaging it.

Bethuel M. Webster

Webster, Sheffield & Horan, New York City

I do not agree that the antitrust laws "have done relatively little since 1890 to protect and preserve a broadly competitive system," or that the results have been negative. It is my view that, while business has grown and flourished under the antitrust laws, it has grown and flourished to a very large extent in a competitive atmosphere. For example, despite the 1941 convictions at Lexington, the tobacco industry, operating under the stringent decree made in 1911, puts out a fine product at low cost in a highly competitive market. One needs only to read the ads or listen to the radio to know that there are four or five major companies and several lesser companies engaged successfully in the struggle for business. The same is true of automobiles, movies, electrical appliances, chewing gum, etc. In the *National Lead* case, recently decided by the Supreme Court, it appeared that, while du Pont and National Lead had 90 per cent of the titanium pigment business (based on patents which they originated and on cartel agreements which the Court

found illegal), subsidiaries of American Cyanamid and Glidden had entered the field and were gaining on the larger producers; meanwhile, there was a terrific struggle between du Pont and National Lead for customers and orders, though the prices of their similar products were substantially identical.

It is the fashion to say that the antitrust laws have never been enforced, or at least that they were not enforced until Thurman Arnold undertook to enforce them in his unique way, and that they have failed to protect and preserve a competitive system. This may be true in the sense that in 1890 Congress did not foresee the enormous industrial development ahead and that the Sherman Act was not calculated to, and has not, protected and preserved a decentralized economy consisting of many small independent units. (Business is unquestionably Big and getting Bigger.) The legislation of the "New Freedom" of 1914 was intended to have such an effect, but by that time industry and business in general had developed in such a way and to such an extent that the Clayton and Federal Trade Commission Acts could not effectively arrest the trend.

The word "negative" is frequently used in this connection. It means different things in different contexts, but to me it means nothing if it suggests that the deterrent effect of the laws has been insubstantial. I think that, by and large, businessmen, even big-businessmen, desire and try to obey the law, and whether they wish to obey or not are required to make their plans and act with reference to the law. This is an important positive effect, just as the effect of the Securities and Exchange Act, or the laws against issuing false statements, or indeed any other law having commercial application, establishes a public policy to which business generally conforms.

Summary Observations

I take it that the participants in this symposium are in general agreement that the antitrust laws (and their enforcement) have not been without influence in shaping the structure and performance of the American economy. The influence which seems to have been most clear-cut is that of blocking agreements between enterprises in the same line of business to fix prices and other terms of sale of products which otherwise would be competitive in these particulars.

I take it that it is equally clear that there is not agreement among the participants as to whether or not the influence of the antitrust laws has been such as to "preserve a broadly competitive system in the United States." Opinion here ranges all the way from a feeling that the laws have been successful in this regard to a feeling that they have been so unsuccessful that it is unwise to rely upon them longer as a major device to make business serve the public interest by responding fully to the dictates of competition.

As one cruises back and forth over this remarkably broad range of opinion one fact seems to emerge with increasing clarity. This fact, stressed directly or indirectly by participants in the discussion, is that the concepts of competition and of a "broadly competitive system" are so diverse that they offer wide latitude for difference of opinion as to the effectiveness of the antitrust laws in preserving and protecting such a state of affairs.

More specifically, in the going concepts of competition there seem to be two major ingredients which are mixed in quite variable proportions. One is performance in buying and selling. The other is the number and relative size of the participants in this process. Thus, according to one going concept of it, competition approaches zero as the number of competitors moves the last few numbers in the same direction. In another concept, the competition may not even get really lively until a few giants are left alone in the ring to slug it out.

It is not my intention even to try to resolve what at times may obviously be a confusing conflict between these concepts, and a conflict which I am sure has afflicted me personally. Both concepts seem to me to have their use, with the element of size and power being perhaps particularly important in trying to gauge the kind of economy that is safe for democracy. That is where my personal interest in the antitrust laws has its mainsprings.

My purpose is simply to note that until we expose the various and complicated strands of our concepts of competition, and then put them together in a clear-cut design which we all understand and accept, our chances of charting clearly how well we are doing in preserving and protecting competition will be seriously compromised. Likewise, until we know much more than now appears to be known about relationships between size, industrial and corporate, and technical efficiency it seems to me that efforts to preserve a competitive system without paying excessively in the form of industrial inefficiency will go forward in a deep fog.

One of the participants in this symposium asserts that "a choice must be made between (1) firms of the most efficient size but operating under conditions where there is inadequate pressure to compel the firms to continue to be efficient and pass on to the consumer the benefits of efficiency and (2) a system in which the firms are numerous enough to be competitive but too small to be efficient." Scarcely less explicitly other participants deny that any such disagreeable choice is necessary. In most industries it does not appear to me that a full appeal to the facts has been made.

In the meantime, there appears to be substantial agreement among the participants that antitrust laws would have accomplished much more than they have accomplished in attaining their ends if there had not been shortcomings such as judicial bungling of economic problems, conflicts, inconsistencies and loopholes in administration, and inadequate support for enforcement. In some cases the remedies for these shortcomings look difficult. If it is true, as one participant asserts, that the courts alone possess enough prestige to have a chance to enforce the antitrust laws effectively, elimination of judicial bungling of the economic problems involved is not likely to be a speedy process. Economic education is not a high-speed acquisition. Likewise, the problems presented by pressure groups bent upon gutting the antitrust laws have no easy or simple solutions.

However, if there is a chance of doing an effective job in the field of antitrust law enforcement (I am not yet persuaded that there is not), it will certainly be greatly enhanced by economic analysis of the problems involved which is more firmly buttressed factually. If there is no chance of

Price Flexibility and Full Employment: Comment

I should like to suggest two corrections in Mr. Don Patinkin's article "Price Flexibility and Full Employment" in the September, 1948 issue of the *American Economic Review*.

1. Mr. Patinkin points out that Pigou's proposition that a decline in the price level will reduce savings and stimulate employment by increasing the real value of cash balances implies a special definition of "cash balances." The "cash balances" relevant to Pigou's argument consist of "the net obligation of the government to the private sector of the economy." This departure from usual definitions of money is necessary because to the extent that money is backed by bank loans and discounts the gains of deposit holders from a decline of prices are offset by the losses of bank debtors. The cash balances relevant to Pigou's analysis are denoted by M_1 .

There follows a statement of considerable importance for monetary policy. Speaking of open-market operations Patinkin says: "Since these operations merely substitute one type of government debt (currency) for another (bonds), they have no effect on M_1 , and hence no direct effect on the amount of savings" (p. 551).

This statement is incorrect if the open-market operation has any effect on the market prices of government bonds, as is likely to be the case. Open-market purchases would increase M_1 , even if private holdings of government debt are valued at par or in some other conventional way. They would increase M_1 even more if the government debt is valued at market prices. Thus, suppose that before the open-market purchases the private sector holds \$10 billion of currency and government bonds worth \$100 billion at par and also at market. $M_1 = \$110$ billion. The government buys \$20 billion, par value, of the bonds, and in the process drives up their price so that it pays \$21 billion for its purchases and at the end of the operation bonds stand at 110 in the market. If bonds are valued at par for the purpose of measuring M_1 , M_1 will have increased to \$111 billion (\$31 billion currency plus \$80 billion bonds). If bonds are valued at market, M_1 will have risen to \$119 billion (\$31 billion currency plus \$88 billion bonds).

Mr. Patinkin's analysis does not postulate any floor to interest rates above zero. If we then assume a world in which all government interest-bearing debt is in the form of consols there would seem to be no limit to the increase in M_1 that can be brought about by open-market purchases so long as any government interest-bearing debt is outstanding. Open-market purchases could push the yield of the consols down toward zero, raising their aggregate market value toward infinity.

If this analysis is correct, open-market operations are a third way of increasing real cash balances in addition to the two mentioned by Patinkin,

falling prices and government deficits. This third method has important mechanical and political advantages that make it a valuable ingredient of stabilization policy.

2. Mr. Patinkin defines M_1 as "the sum of interest- and noninterest-bearing government debt held outside the treasury and central bank" (p. 551). This definition is used in the measurement of M_1 on page 559. The definition is defective in its treatment of gold and federal debt held by the Federal Reserve Banks. Under this definition an inflow of gold, increasing the public's deposits and member bank reserves would not increase M_1 . Neither would M_1 be increased if the Treasury sold securities to the Federal Reserve using the proceeds to pay individuals who hold deposits. If the Federal Reserve is to be treated as part of the government, the Federal Reserve's liabilities, including member bank reserve balances, should be treated as government liabilities. If the Federal Reserve is not to be treated as part of the government, the government's liabilities should include its liabilities to the Federal Reserve.

M_1 would be better defined as gold stock plus federal debt (interest-bearing and Treasury currency) held outside Treasury, minus Treasury deposits at Federal Reserve and other banks. Alternatively, looking at the Federal Reserve as part of the government, we get M_1 equal to money in circulation plus federal debt held outside government and Federal Reserve Banks (this is Patinkin's definition) plus member bank reserve balances, plus non-member bank deposits at Federal Reserve, plus "other Federal Reserve Accounts," less Treasury deposits outside Federal Reserve Banks less Federal Reserve credit other than U. S. governments. These two definitions are identical.

HERBERT STEIN*

Price Flexibility and Full Employment: Reply

1. Both of Mr. Herbert Stein's corrections are well taken, and I am glad to have them on record. There are just a few comments I would like to make.

Mr. Stein seems to be hesitant about evaluating at market prices those bonds remaining unsold. I think this should definitely be done; so, in the example he offers, M_1 should be considered as increasing from \$110 to \$119 billions. Once we adopt this approach, the possible effects of open-market purchases become still greater; for, through its effect on the interest rate, the government will also change the value of assets other than government securities.

Even apart from this last point, it should be recognized that the changes in M_0 and M_1 will not in general be equal. In the case of open-market purchases, the increase in M_0 equals the total amount of money expended for the purchase of the bonds; the increase in M_1 equals the increased value of assets (both of those bought and those not bought by the government) caused by the open-market operations. Corresponding statements can be made for open-market sales.

To finish up with Stein's first point, I would dispute the emphasis in his statement that "open-market operations are a third way of increasing real cash balances in addition to . . . falling prices and government deficits." Nominally, Stein is correct. Actually, open-market purchases which bid up bond prices are just a special form of deficit financing. When the operation is completed, the total amount of government debt (interest- as well as non-interest-bearing) has increased. All that has happened is that the composition of the debt has changed. Any criticism levelled against deficit financing via, say, tax remissions, can also be used against open-market operations.

2. In the original article, the definition of M_1 given in §6 refers to an economy in which all bank reserves consist of hand-to-hand currency. Unfortunately, this definition was carried over to the analysis of our own economy (pp. 558-59), where there are also debtor relationships between the Federal Reserve System and the private sector. Stein's modifications of the definition of M_1 allow for these relationships. Milton Friedman has also suggested that postal savings be included.

Even these modifications do not solve all the problems of defining M_1 in an economy as financially complicated as ours. What about state and local bonds? I think these should be excluded because of the ultimate necessity of these local governments to balance their budgets. What about bonds of government corporations? I think these should also be excluded, for the same reason. In any empirical study of the effects of changes in M_1 , these and other complicated problems will first have to be solved.

These changes in the definition of M_1 require the recomputation of the data on page 559 of the article.¹ In order to be perfectly clear about the steps used in the computation, I shall first explicitly state the definition of M_1 used, at the expense of repeating some of the material in Stein's note: M_1 equals:

- (1) money in circulation outside the Treasury and Federal Reserve System
- (2) *plus* market value of government interest-bearing debt held outside government agencies and the Federal Reserve System
- (3) *plus* member bank deposits in the Federal Reserve System
- (4) *plus* non-member bank deposits in the Federal Reserve System
- (5) *plus* other Federal Reserve accounts
- (6) *minus* Reserve Bank credit outstanding, excluding that based on Reserve Bank holdings of U. S. government securities
- (7) *minus* Treasury deposits in member and non-member banks
- (8) *plus* postal savings

Data on these series were collected² to yield the following figures for net

¹ The study referred to in footnote 19 of the article must also be revised. This has not yet been done.

² Data on all these series, except for (2), (7), and (8), can be obtained from *Banking and Monetary Statistics*, p. 368. On pp. 360-67 of this book their interrelationships are discussed. For (7) see *ibid.*, pp. 34-35. For (8) see *Statistical Abstract of the United States: 1947*, p. 419.

Being unable to find an official series for (2), I used the following procedure: Total

real balances in the years 1929-1932, respectively: \$16.6, \$17.1, \$20.3, and \$24.2 billions. These results give even less encouragement than the original ones for faith in the usefulness of the Pigou effect as a policy measure. They show that real balances increased every year of the period, while real national income continued to fall. The year-to-year *increases* of net real balances for this period were 3%, 19%, and 19%, respectively; these were matched by corresponding *decreases* in real national income of 15%, 13%, and 18%,^c respectively.

Before accepting the Pigou effect as a useful tool of policy, it would seem reasonable to require that a 46% increase in real balances should show at least some salutary effects. This is exactly the percentage increase that took place over the period 1929-32. Yet it was accompanied by a *decrease* in real national income of 40%. To say the least, such evidence should make one hesitant about advocating the Pigou effect as a practical policy measure.⁸ True, the above data do not take into account what happened to the real value of all assets during this period (*cf.* §5, especially footnote 6, of the original article). But, with respect to policy, monetary assets (as represented by M_1) are the only ones over which the government has any control. Hence, the case for the Pigou effect must stand or fall on the response of the economy to changes in the real value of monetary assets alone. On this question the available evidence seems definitely in the negative.

DON PATINKIN*

outstanding government debt at face value was classified according to maturities (0-5 years, 5-10, and over 10) on the basis of *Banking and Monetary Statistics*, p. 511. These classifications were multiplied by price indexes for government bonds with maturities of more than 3 and less than 4 years, more than 6 and less than 9, and more than 10, respectively (Standard and Poor, *Statistics: Security Price Index Record: 1948 edition*, pp. 139-44). The sum of these products was used as an estimate of the market value of the total government debt. The ratio of this to the face value of the total debt was computed, and this ratio applied to the face value of government debt held outside the Treasury and Federal Reserve System (*Banking and Monetary Statistics*, p. 512) to yield an estimate of the required series.

⁸ In particular, I feel that Milton Friedman's policy proposals in his "A Monetary and Fiscal Framework for Economic Stability" (this *Review*, June, 1948, pp. 245-64) give entirely too much of a central position to the Pigou effect (*cf.* especially *ibid.*, pp. 259-61).

* The author, formerly associate professor of economics at the University of Illinois, is now lecturer in economics at the Hebrew University in Jerusalem.

Geometrical Measurement of Elasticities

Messrs. John S. Henderson and Abba P. Lerner, in notes presented in *The American Economic Review*,¹ have suggested methods of geometrical comparisons of relative point elasticities on different curves.

When comparing the point elasticities of two demand curves, it is sometimes

¹ John S. Henderson, "Geometrical Note on Elasticity of Demand," *Am. Econ. Rev.*, Vol. XXXVI (Sept., 1946) pp. 662-63.

Abba P. Lerner, "Geometrical Comparison of Elasticities," *Am. Econ. Rev.*, Vol. XXXVII (March, 1947) p. 191.

desirable (under a controlled marketing program, for example) to know not only which of the two elasticities is larger, but the ratio of the elasticities. Comparison of relative point elasticities on two demand curves by the ratio of two length ratios may be confusing. The following method is suggested to reduce the ratio of the elasticities to a single ratio of two line segments, illustrated by the diagram shown below:

The elasticity at V, $E_v = \frac{AB}{OA}$, the elasticity at W, $E_w = \frac{CD}{OC}$. With O

as center swing an arc equal to OC cutting AV extended at C'. At B erect a perpendicular and extend to cut OC' extended at P. Since BP is parallel

AC', $\frac{AB}{OA} = \frac{C'P}{OC'}$ (a line drawn through a triangle parallel to the base

divides the sides proportionately), or since $OC' = OC$, $\frac{AB}{OA} = \frac{C'P}{OC}$. Then,

with C as center, and C'P as radius, swing an arc cutting the q axis at P'.

Thus $E_v = \frac{AB}{OA} = \frac{C'P}{OC}$, and $E_v : E_w = \frac{C'P}{OC} : \frac{CD}{OC}$ or $E_v : E_w = C'P : CD$.

MEMORIALS

Wesley Clair Mitchell 1874-1948

On December 28, 1947, at the sixtieth annual meeting of the American Economic Association in Chicago, Wesley Clair Mitchell received the first award of the Francis A. Walker Medal for pre-eminent contributions to economics during a lifetime of distinguished service. In a graceful tribute President Douglas expressed the admiration and affection in which Professor Mitchell was held by the economists of America. Mitchell's death came ten months later. It is a source of deep satisfaction to all members of the Association that opportunity was given while Mitchell was yet alive for the expression of our feeling for him, and for the acknowledgment of our indebtedness to him. We knew then, as we know now, that the award was made to one of the great figures in the history of our science.

I

Wesley Clair Mitchell was born in Rushville, Illinois, on August 5, 1874. His father was a country doctor who had served as a surgeon in the Union Army during the Civil War. The family was of New England stock, and although a Middle Western boyhood and later adult years in California and New York left their impress on Mitchell, something of the New England strain was always discernible in the pattern of his thought and life. His father's practice, which was limited by the effects of wounds received during the war, was combined with the management of a fruit farm on which the seven children worked during their early years.

Mitchell's pre-college schooling followed the pattern of the times, but home influences and his own native qualities contributed to produce a mind that was keen, sensitive, and richly stocked before he left the farm for college work. He had an abiding love of poetry and a delicate awareness of the subtleties of speech and the rhythms of the English language—qualities that must be acquired early, or not at all. His youthful training in logic he has described with singular charm. Christian theology was the instrument on which he polished his youthful wits, and a well-loved grand aunt was the protagonist of this theology.

She was the best of Baptists, and knew exactly how the Lord had planned the world. God is love; he planned salvation; he ordained immersion; his immutable word left no doubt about the inevitable fate of those who did not walk in the path he had marked. Hell is no stain upon his honor, no inconsistency with love. . . . I adored the logic and thought my grand aunt flinched unworthily when she expressed hopes that some back stairs method might be found of saving from everlasting flame the ninety and nine who are not properly baptized. But I also read the Bible and began to cherish private opinions about the character of the potentate in Heaven. Also I observed that his followers on earth did not seem to get what was promised them here and now. I developed an impish delight in dressing up logical

"difficulties which my grand aunt could not dispose of. She always slipped back into the logical scheme, and blinked the facts in which I came to take a proprietary interest."¹

The young University of Chicago offered rich fare to a mind thus prepared. John Dewey provided a kind of logic that was far removed from that of nineteenth-century theology, and a way of regarding the operations of the human mind that was a revelation to the young student. "It is a misconception to suppose that consumers guide their course by ratiocination—they don't think except under stress. There is no way of deducing from certain principles what they will do, just because their behavior is not itself rational. One had to find out what they do. That is a matter of observation, which the economic theorists had taken all too lightly."² Thorstein Veblen provided edification of another sort for the youthful agnostic with a weakness for subtle paradoxes. Veblen's influence on Mitchell was profound (the paper on "Industrial and Pecuniary Employments" provided insights that helped shape the study of business cycles and much of Mitchell's later thinking); but the young student could view Veblen, too, with detachment, enjoying his brilliant expositions and sardonic style while appreciating that this, also, with all its penetrating suggestiveness, fell short of sound craftsmanship. ("How important were the factors he dealt with and the factors he scamped was never established.")

Somewhat more conservative approaches to economics were open in the well-documented course of Adolph C. Miller on English economic history, and in J. Laurence Laughlin's offerings in money and banking. Mitchell's first serious investigations and his early undertakings as a teacher reflected Laughlin's influence. His study of the greenbacks stemmed directly from Laughlin, and Mitchell was first introduced to the phenomena of business cycles in Laughlin's courses. One other of Mitchell's teachers of economics, William Hill, played a formative role at this stage. An assignment by Hill of a course paper on "Wool Growing and the Tariff" sent Mitchell first to the reading of tariff speeches—an illuminating experience in its own right—and thereafter to his first comprehensive job of data gathering. Mitchell's native agnosticism was strengthened by the contradictions he found between his statistical conclusions and the notions he encountered in Congressional and academic discussions of the tariff.

Unsystematic but fairly extensive readings in anthropology (instigated by Veblen) and some systematic course work in psychology carried Mitchell beyond the programs of study followed by most students of economics. This period brought, too, first contacts with Jacques Loeb, the brilliant physiologist. Loeb's studies of the phenomena of behavior at both the physiological and

¹Letter from W. C. Mitchell to J. M. Clark, published in *Methods in Social Science*, edited by Stuart Rice (Chicago, 1931), p. 676.

Years later, on declining an invitation to make some laudatory remarks that would have been hypocritical, Mitchell said that only once in his life had he expressed views that did not represent his convictions. He had made this one departure from probity to ease his grand aunt's forebodings.

²*Ibid.*, p. 677.

psychological levels influenced Mitchell not only in their substance, but as illuminating examples of scientific method. Loeb gave Mitchell positive, first-hand acquaintance with rigorous methods that were clearly fruitful in studying one aspect of organic behavior. Mitchell was prepared to appreciate their potential fruitfulness in dealing with other aspects of behavior. Here were instruments that offered something positive and satisfying to a mind rendered skeptical by early predilections, by Veblen's biting critiques, and by Dewey's iconoclastic treatment of conventional attitudes toward processes of thought. Loeb's influence on Mitchell, confirmed and strengthened through later association at California, was deep and lasting.

In this background we have some explanation of Mitchell's ability to get outside the framework of traditional economics, to view with a fresh eye the problems economists set themselves and to appraise from a fresh viewpoint the methods employed by economists in attacking these problems. The projection of these factors helps, too, to explain Mitchell's characteristic attitudes in later years, and his own choice of problems and methods.

Mitchell's undergraduate and graduate studies at Chicago were broken by an interim period of one year spent at Halle and Vienna, where he attended lectures by Johannes Conrad and Carl Menger. There is no evidence that this experience had any material influence on Mitchell's thinking. His outstanding qualities as an economist were distinctive of procedures and ways of thought that had their characteristic development in this country.

Mitchell's doctorate was completed at Chicago in 1899, his thesis being a *History of the Legal Tender Acts of 1862 and 1863*. Thereafter came a year at the Office of the Census and two years at Chicago as instructor in economics. During this period his doctoral dissertation was expanded to become a *History of the Greenbacks*, a notable study in itself and a point of departure for much of Mitchell's later work.

In 1903, Mitchell moved to the University of California at Berkeley to begin a decade of fruitful work and of steady personal growth. His tools of research were sharpened and his mastery of them perfected. His brilliant greenback studies were extended. But the confines of this enterprise were too narrow, and Mitchell soon laid it aside. (*Gold, Prices and Wages Under the Greenback Standard* contains basic data he thought it well to make available to other scholars, with explanatory notes, but the material was not fully exploited.) Some of the essential problems with which he was concerned in his first studies persisted, but Mitchell sought to solve them in a much wider framework, analytical and observational. The massive monograph on *Business Cycles*, one of the great products of scholarship in the social sciences, was the result.

The labors that led to the solid contributions of these California years did not preclude other activities. This was a rich period in Mitchell's life, to which he always looked back as something of a personal golden age. A young man intellectually somewhat aloof and inclined toward austerity mellowed in the sunshine of the West and in the easy, pleasant companionships of the young University. His associations within and without his own department were congenial. An active Philosophical Union helped to provide

intellectual fare. He took to the Sierras avidly, relishing the free ways, the free language and the physical release to be found in mountain climbing. A companion of those days says that Wesley's inhibitions were peeled off like the layers of an onion as successive altitude levels were passed. He found a wife, too, in the West; when he left California he took with him the Dean of Women of the University.

Mitchell ended his term at California in 1912. Marriage and the completion of his *Cycles* study combined to mark the end of one period of his life and the beginning of another. His own professional desires and the interest he and his wife shared in problems of education were both served by a move to New York. There was a break of one year which was spent abroad; final tables for *Business Cycles* were prepared at Berchtesgaden, when that word meant merely a beautiful spot in the Bavarian Alps.

On his return to the United States in 1913, Mitchell began his service in the Faculty of Political Science at Columbia. The department of economics was small in those days. J. B. Clark was still meeting students occasionally; Seligman, Seager, Simkhovitch and Moore were the continuing members of the teaching staff when Mitchell joined it. None who attended Mitchell's courses in those early years will forget the sense of excitement and anticipation with which one entered a class. Mitchell was giving a course on *Business Cycles*, a reflection of his continuing research interests. Equally stimulating to the students of that day was his new offering on *Types of Economic Theory*. Mitchell's early discontent with economic theory, a discontent clearly manifest in his own account of his student days,³ had been combined with a sense of the need of generality if we are to have adequate explanations of complex reality. There was a conviction of need, a profound unhappiness over what was offered. *Business Cycles*, indeed, had been regarded by Mitchell as an introduction to economic theory. The completion of that study gave Mitchell opportunity to turn to a more systematic review and appraisal of theory than he had yet undertaken. This he did in the years following 1913, and the members of his small classes had opportunity to join in this review with him.

The content of this course varied somewhat from year to year. In its early form it included expositors of English classical doctrines through Marshall;

³ "Men had always deluded themselves, it appeared, with strictly logical accounts of the world and their own origin; they had always fabricated theories for their spiritual comfort and practical guidance which ran far beyond the realm of fact without straining their powers of belief. My grand aunt's theology; Plato and Quesnay; Kant, Ricardo and Karl Marx; Cairnes and Jevons, even Marshall, were much of a piece. Each system was tolerably self-consistent—as if that were a test of 'truth'! There were realms in which speculation on the basis of assumed premises achieved real wonders; but they were realms in which one began frankly by cutting loose from the phenomena we can observe. And the results were enormously useful. But that way of thinking seemed to get good results only with reference to the simplest of problems, such as numbers and spatial relations. Yet men practiced this type of thinking with reference to all types of problems which could not be treated readily on a matter-of-fact basis—creation, God, 'just' prices in the middle ages, the *Wealth of Nations* in Adam Smith's time, the distribution of incomes in Ricardo's generation, the theory of equilibrium in my own day." (From letter to J. M. Clark, Rice, *op. cit.*, p. 678.)

Jevons and Walras; Sombart, Schmoller, Schumpeter and von Wieser; Fetter, Davenport, and, extensively, Veblen. The treatment of each author studied dealt with the substance of that man's thought, and with the social and intellectual setting of this thought. At a later time Mitchell wrote, "Scientific progress consists largely in this process of taking thought about what had theretofore been taken for granted. As any science grows it keeps turning back upon itself in this fashion, and thus becoming conscious of more and more elements in its structure."⁴ Mitchell's native skepticism, his excursions into anthropology and psychology, and his ability to look at traditional economics with an objective perspective admirably fitted him to deal thus with the postulates and preconceptions of various types of theory.⁵

In the conduct of this course Mitchell played the part of a detached and skillful expositor, a leader of discussion, a stimulator of critical appraisal. His treatment of his class was gracious, stimulating; his interpretations were illuminating revelations to most of us. The facts of social history, the character of the climates of political opinion that dominated the years when particular theories were taking shape, and the threads of philosophical thought that ran through these years were developed systematically as the assumptions of different theorists, conscious and unconscious, were laid bare. Mitchell's own views were subordinated, except in his closing lectures, although they were inevitably revealed by implication and indirection. It was clear that a genetic explanation of economic phenomena was congenial to Mitchell's thought; that rationalistic assumptions were suspect; that understanding of economic behavior was to be sought through a study of human motivation at the level of the instinctive and the unconscious as well as at the level of rational activity; that institutions, "prevalent social habits," were at once controllable and controlling in the processes of economic life; that economics could play a major role as a positive instrument of human progress.

This course, like every course that Mitchell gave, was an adventure in education. Mitchell possessed in high degree the qualities of a good teacher. There was insight in his analyses; there was a freshness of view that he never lost; there was lucidity of thought and expression, and masterly orderliness of exposition; there was a sense of sharing with the student the task of inquiry. Above all, perhaps, was the sense of integrity. Here was a man without affectation, without pretense, who honestly sought understanding.

Mitchell's reputation had been established by the time he came to Co-

⁴ "Postulates and Preconceptions of Ricardian Economics," reprinted in *The Backward Art of Spending Money and Other Essays* (New York, 1937), p. 205.

⁵ His distinction between logical postulates, which are consciously recognized and taken for granted, and preconceptions—convictions that shape the general trend of a man's thinking without being themselves submitted to critical scrutiny—is revealing for the light it throws on Mitchell's ever-present suspicion of rational processes. "We take postulates up, play with them, and drop them for others. They are external to us and we feel no affection for them. But preconceptions are parts of us. They grow up in our minds. We are but dimly aware of the role they play in shaping our conclusions about the matters on which we focus attention. . . . Even in our most rigorous work we are influenced by them." *Ibid.*, p. 205.

lumbia; he had reached full scholarly maturity. Yet his growth continued and his accomplishments multiplied. A steady (but not a voluminous) flow of papers, reviews, addresses and more extensive studies came from his pen. Into each, whether brief or extended, went care in the construction of a logical and orderly argument, skill in the marshalling of evidence, and objectivity in the use of that evidence. Each, too, was in exposition a work of craftsmanship by a man who used the instrument of language with sensitivity and precision.

There was also an almost uninterrupted series of public and professional services and of accumulating honors. He was chief of the Price Section of the War Industries Board during the first World War, chairman of the President's Committee on Recent Social Trends, a member of the National Planning Board, the National Resources Board, and the Federal Emergency Administration of Public Works, and chairman of the Committee on the Cost of Living when that burning issue threatened to check the steady production of goods during the second World War. There was the launching in 1920 and the directing for a quarter of a century of a new instrument for the advancement of knowledge—the National Bureau of Economic Research, an institution which in very truth is the lengthened shadow of Wesley Mitchell. Over a long stretch of years he helped to break down the barriers between the social sciences and to unify their activities in the Social Science Research Council. He was one of those who founded and shaped the New School for Social Research. Counsel and guidance were given over many years to the Bureau of Educational Experiments. He was called upon to direct the affairs of professional societies, serving as President of the American Economic Association, the American Statistical Association, the Econometric Society, and the American Association for the Advancement of Science. There were elections to learned societies at home and abroad. Honorary degrees came from the University of Paris and from major universities in this country. These were rich honors and they were not unwelcome; but he remained to the day of his death a modest scholar, who would both gladly learn and gladly teach.

II

The general pattern of Mitchell's work as an economist was foreshadowed in his *History of the Greenbacks*. There was broadening, diversification, and enrichment in subsequent activities, but in notable degree later developments were natural outgrowths of the play of a questing mind on a set of problems first attacked in the greenback study. These problems were products of contemporary conditions—the long period of price decline and debtor difficulties that generated the cross-of-gold speech, the free-silver program, and the sound-money controversy of the McKinley-Bryan campaign. This price decline provided the great economic issue of that day. Its causes were furiously debated within and without academic halls. Francis A. Walker and J. Laurence Laughlin, Mitchell's teacher, were adversaries in a sustained debate on the quantity theory of money. Mitchell's first published paper, written as an undergraduate, was a contribution to this discussion, with

Mitchell taking a highly critical view of that theory.⁶ It was natural that this should be the path by which Mitchell entered upon serious economic study, and that his first major investigation should deal with the issuance of money and with related price-level and other changes. What is notable, however, is the rapid and steady growth, the passage from an old controversy to realistic research on larger issues and more fruitful phases of the inter-relations of money and prices. This growth was steady and cumulative. There is a clear, unbroken thread running through Mitchell's major studies—from the *History* to *Measuring Business Cycles* and to the manuscripts that were left unfinished at his death. Mitchell's life was given to a single great endeavor, pursued tenaciously, imaginatively, flexibly, and unremittingly. In some sense the job was unfinished at his death; the self-imposed task of mastering a vast and shifting body of data was foredoomed to incompleteness; but the incompleteness was the incompleteness of life itself.

Mitchell's concern in his *History of the Greenbacks* was with the economic consequences of the legal tender acts. The pursuit of these consequences led him to an examination of the effects of changes in the purchasing power of the standard money upon the distribution of the national dividend during the wartime boom from 1861 to 1865. The shares in this national dividend, first studied in money terms, through an appraisal of price fluctuations and shifts in relative prices, were then assessed in real terms. Beyond this study of changes in the real incomes of laborers, landlords, capitalists, and business managers lay a broader question—what effects these changes had upon the production and consumption of wealth, again at the level of material things.

In the unfolding story of these four years of monetary depreciation and rising prices we find elements that entered into much of Mitchell's later work: the money level and the real factors underneath; the role of prices and, in particular, the importance of differential price changes in determining the fortunes of different groups; the effects of relative price changes upon profits, and the relations between changes in profits and changes in the rewards of other factors. For a single major phase of wartime expansion Mitchell was seeking to define the sequence of cumulative changes by which depreciation of the standard of values altered the system of money payments and thereby shifted the distribution of real income. But his study was restricted in time and its scope was confined to a limited number of economic processes. Before this and the closely related successor study were finished Mitchell knew that he had not gotten to the bottom of the problems he faced; he had, moreover, learned to see these problems in a larger way.

Renouncing, therefore, the limited study within the period of the greenback episode, Mitchell turned first to a more general analysis of the system of prices. Here, as he followed the interesting ramifications of this subject, he found himself leaving the solid ground of observation behind him and venturing into speculative pronouncements.⁷ This was intolerable to a man

⁶ "The Quantity Theory of the Value of Money," *Journal of Political Economy*, March, 1896.

It was not many years before Mitchell himself condemned the restricted conception of the quantity theory on which the argument of this paper was based. See "The Real Issues in the Quantity Theory Controversy," *Journal of Political Economy*, June, 1904.

⁷ Cf. Rice, *op. cit.*, p. 679.

who was always supersensitive to the dangers of unchecked reason. But one phase of the working of the price system was open to investigation in realistic terms—the recurring readjustments of prices in the course of financial crises. These shifts, moreover, bore upon those problems of changing real output and consumption and shifting real incomes that had been objects of central concern in his study of the Civil War expansion. If adequate understanding of these recurring processes might be achieved, a contribution could be made to a kind of economic theory more satisfying than that yielded by introspection and the selective use of limited facts. So Mitchell turned to the study of business cycles.

The subsequent story will not here be told in detail. The search for an adequate understanding of business cycles was a search for valid economic theory. Mitchell's examination of accepted theories, his extended consideration of relevant thought and procedures in other scientific fields, and his own experience as an investigator led to conclusions respecting theory that have been set forth in various papers and that are embodied in his substantive work. Mitchell's persistent interest in the phenomena of business cycles carried through to his death, the two major publications subsequent to the 1913 monograph being *Business Cycles: The Problem and Its Setting*, in 1927, and *Measuring Business Cycles* (jointly written with A. F. Burns) in 1946. The founding of the National Bureau of Economic Research, in which Mitchell was a prime mover, was a direct reflection of Mitchell's deep-seated views as to the means by which adequate understanding might be achieved. The diversity of papers and brief monographs, notably the series of annual reports written by Mitchell as director of the National Bureau, bore continuing witness to the freshness and seminal character of Mitchell's thinking, and reflected the searchings of a continually curious mind for light on the central problems that had concerned him from his early Chicago days. His quest was never finished, but his zest for it was unabated and unflagging.

Mitchell's concern, as J. M. Clark has suggested, has been with problems of concrete behavior. For these he sought interpretations in terms of "analytic descriptions."⁸ "A theory of business cycles," he wrote in the Preface to his 1913 monograph, "must . . . be a descriptive analysis of the cumulative changes by which one set of business conditions transforms itself into another set." The theory providing such descriptive analysis would not be exhaustively detailed. The need of abstraction from the complexities of reality is clearly recognized by Mitchell. Conformity to the world about us and usefulness in the understanding of life processes are not inconsistent with conceptual simplicity. Mitchell's goal in the study of business cycles was the derivation of such a theory; his broader objectives were the confirmation of methods by which pragmatically tested theories might be derived and the establishment of agencies by which the research that might lead to such theories could be maintained and assured.

The road that Mitchell followed in seeking to establish theories that would serve as instruments of understanding was a hard road. Looking back over the fruitful years of his life, it is easy to overlook the valleys, the periods

⁸ Cf. Rice, *op. cit.*, p. 667.

of trial and struggle when refractory reality would not fall readily into patterns that met his own exacting standards. Retreat into the spinning of speculations would have been an easy way out, for a mind as adept at that art as was Mitchell's. But this was a course he did not take. He worked over his materials again and again ("... I have to do everything a dozen times."); he sought new observations; he experimented with new patterns. Always there was the interplay and interaction of reason and observation; speculations were checked against data, data were organized in ways suggested by speculation. New observations were sought to check ideas suggested by other data; old observations were re-ordered under the play of an imagination that never lost its freshness. If there was one dominant quality in Mitchell it was the tenacity with which this procedure—the interplay of speculative reason and meticulously careful observation—was carried through. It is a procedure to which we all give lip service; Mitchell practiced it.

It is true that always the observations yielded an incomplete structure; always there were challenging new issues; always the work was unfinished. But this was of the essence of the reality from which Mitchell refused to get away. Not even for the aesthetic satisfaction of deriving a harmoniously consistent, logically tight system—and Mitchell was a craftsman who loved nicely articulated structures—would he blind himself to aberrant observations. Not even for the joy of completing a lifework would he ignore any part of the complex reality with which he was dealing. Here was integrity—integrity that kept him at his testing and pattern-making until the day of his death, and that kept beyond his reach that final clean-cut termination of his job for which he had once hoped.

Mitchell framed no vast speculative system. He left no cosmology. No volume of *Principles* bears his name. His substantive contributions are embodied in four major monographs; his influence on economic thought and method was felt through these, through dozens of papers, addresses and reviews, and through hundreds of students. Some of the concepts and beliefs that shaped his research activities have been suggested above:

1. The emphasis on objective behavior as an object of study, as against the "intellectualist fallacy" of the nineteenth century.
2. The conception of economics as one of the sciences of human behavior.
3. A concern with reality, and a conviction that the objective of economics is the understanding of the institutions and processes by which men make their livings. All available instruments to this understanding should be utilized by the economist, but it is the understanding of reality and not the formulation of a body of concepts to be judged in terms of their own internal consistency which is the end-purpose of economics.
4. The belief that pecuniary institutions, and the money economy generally, provide keys of central importance to an understanding of contemporary economic processes.
5. The notion of sequence, the concept of cumulative, consecutive growth, as opposed to the Newtonian concept of equilibrium.
6. "The notion that inquiries should be framed from the start in such a way as to permit of testing the hypothetical conclusions"; profound belief

in the interplay of reason and observation as the way to achieve warranted conclusions.

7. The confidence in statistical measurement as a means of ensuring the cumulative growth of a body of factual knowledge; such quantitative, substantive knowledge would not only provide tests of hypotheses, but would constitute a seed-bed for the germination of new hypotheses.

These ideas (as here listed they overlap, of course) and related concepts that determined Mitchell's choice of problems and modes of study were derived in part from early teachers and from his studies in various fields; in part they reflected personal predispositions; as working instruments of his adult years they represented his own amalgam of thought and observation and his own mature judgments. From their application over half a century by a tenacious, questing, honest mind, actuated by a builder's instinct, came Mitchell's distinctive contributions to the body of economic knowledge, to the methods of economics, and to our present instrumentalities for the conduct of economic and social research.

The nature of these contributions will be the subject of appraisal in subsequent studies by Mitchell's fellow economists at home and abroad. In this brief memorial I suggest only the general nature of Mitchell's impact on the economics of his time.

His substantive contributions were extensive. No man did more to turn economists toward the study of the actual functioning of our economic system. The first great effort on *Business Cycles*, an extraordinary product of the zeal and energies of one man, yielded knowledge we had never before possessed of the phenomena of such fluctuations; the play of an imaginative and penetrating mind illumined and gave coherence to these phenomena. Subsequently, this body of organized information was extended in a massive and sustained research effort covering more than a quarter of a century. Many contributed to this accumulation and participated in the task of analysis, but Mitchell was the stimulator and the master organizer.

There were concrete contributions beyond the field of cycles. Mitchell was the captain of the team that launched the first comprehensive study of the amount and distribution of the national income. From this came not only a new body of knowledge vital to an understanding of economic activity; an enterprise was begun that was ultimately taken over by the federal government, and that, expanded and developed, provides today a great conceptual scheme for the organization and analysis of the facts of economic life. The growth of the body of concepts and methods relating to national income and the concurrent development of a rich body of organized facts provide an ideal example of the kind of expansion of knowledge in which Mitchell believed and to which he devoted his life.

Finally we must note the additions to our knowledge of the details of the working of the money economy that derive from Wesley Mitchell. Veblen had stressed the role of pecuniary institutions in the behavior of men; Marshall had said that money is "the center around which economic science clusters"; Walras and Pareto had developed a model defining the interaction of prices in the attainment of market equilibrium. And many other economists

had dealt with the money surface of things, often as a surface that obscured the play of real factors. Mitchell found great theoretical significance in the money aspect of economic processes. But to point this out was not enough. Characteristically, he labored to give substance to these ideas. From his earliest greenback study to his latest manuscript Mitchell was providing such substance. Giving realism to the idea of prices as a complex, interrelated system of many parts, with almost organic qualities of growth and change, Mitchell defined the characteristic modes of behavior of important elements of that system. The systematic study of prices, not primarily as specific equilibrium points in a conceptual network of supply and demand schedules but as measurable aspects of economic behavior, began with Mitchell.

Mitchell was a tool-maker, imaginative and ingenious in improving the technical instruments of research. His monograph on index numbers is still a classic in the field. In his own early work he developed novel techniques of cycle study, and he played a continuing part at the National Bureau in the refinement of these tools and the forging of others. He was not a mathematical statistician, but he had a lively interest in this rapidly developing subject and sought to utilize in his own work such of the tools and tests as he could employ with understanding and with assurance that they were relevant.

The perspective of time will be needed for an appraisal of Mitchell's influence on the body of concepts and analytical tools suggested by the term "economic theory." In the revealing letter to J. M. Clark to which reference has been made Mitchell has described his own reaction to the traditional theory of his college days. He was impressed by the danger of speculation on the basis of assumed premises, except with reference to the simplest of problems, such as numbers and spatial relations. Where *phenomena* were to be explained one could not cut loose from them; here the "patient processes of observation and testing—of the relations between working hypotheses and the processes observed" were the roads to understanding. "Romances, utopias, and economic systems" (*i.e.*, systems of economic thought) he loved, but he wanted to become a scientific worker.⁹

Theory, then, as an abstract system of thought which could not be tested against reality, had no place in Mitchell's working equipment. But theories as working hypotheses that can be checked against observations, as analytical devices that facilitate the organization of data, are to be sought and prized. These tools may be specific and limited; they may be comprehensive and far-reaching concepts; indeed an architectonic mind—and this Mitchell had in high degree—would be forever seeking the widest possible framework, the most comprehensive concepts, provided always that the framework fitted reality, that the concepts were open to testing and verification.

The body of ideas on which the economist might draw in deriving working hypotheses expanded, in Mitchell's thinking, as he matured and as his own experience broadened. The social sciences, the biological sciences, the sciences of the mind—all these furnish the economist with fruitful leads. Man's

⁹ Rice, *op. cit.*, p. 678.

reciprocal relations with institutions of his own contriving, institutions which he has shaped and which in turn are shaping him, are of central concern to one who is attempting to define patterns of cumulative change in economic behavior and to develop a body of concepts for use in the study of economic processes. This body of concepts will be checked, modified, rechecked and again modified until there is conformity to the circumstances of economic life. A structure of ideas thus developed and thus adapted to reality would provide intellectual tools for the understanding of economic behavior.¹⁰

Although Mitchell's predilection was toward inductive procedures and constant verification, and although he reacted against the system building of the generation that preceded his own, he recognized virtue in a diversity of approaches to economic problems. He was intolerant of sheer abstraction which masqueraded as an explanation of reality. But for rigorous abstract reasoning as a stage in the process of inquiry he had the fullest respect. There was room in economics for the exercise of many skills; economics was to Mitchell a house of many mansions.

III

To the picture of Wesley Mitchell the tenacious investigator, the brilliant expositor, the inspiring teacher, there must be added a few strokes at least to depict other sides of a singularly balanced human being. There was a Puckish quality in Mitchell reflected in his youthful (and enduring) love of paradox. Even in his advanced years he could view with impish glee Irving Fisher's soberly framed rules of health; he used tobacco with special gusto because Fisher banned it. He enjoyed the play of Veblen's scalpel,

¹⁰ There is no one source in which Mitchell's views on economic theory are set forth in rounded form. Certain of his essays deal more explicitly with these matters than do his extended works. Three papers reprinted in *The Backward Art of Spending Money and Other Essays* are of direct interest: "The Role of Money in Economic Theory," *American Economic Review*, Supplement, March 1916; "The Prospects of Economics," from *The Trend of Economics*, edited by R. G. Tugwell, 1924; "Quantitative Analysis in Economic Theory" (Presidential address delivered at the 37th annual meeting of the American Economic Association), *American Economic Review*, March 1925.

To these we might add "Wieser's Theory of Social Economics" (*Political Science Quarterly*, March 1915; also reprinted in *The Backward Art of Spending Money and Other Essays*). In expounding Wieser's theory, Mitchell makes clear many of his own ideas on the scope and character of a useful body of economic theory.

Not explicitly devoted to theory, but of high significance for the light they throw on Mitchell's basic conception of theory, are chapters on institutional settings in his 1913 and 1927 books on *Business Cycles*. In the earlier book the chapter is entitled "The Economic Organization of Today"; in the later, "Economic Organization and Business Cycles."

Mitchell's opinions as they stood in 1918 were rather systematically, although informally, developed in the terminal lectures in his course on Types of Economic Theory, in which he propounded a modern ground plan for economic theory. Notes on these lectures exist, but they were never edited by Mitchell, or approved by him. In these lectures Mitchell sketched a general framework in which economics was presented as one of several sciences of human behavior, the special concern of economic science being the growth and present functioning of economic institutions. Into such a framework all the traditional types of economic theory, as well as types involving other approaches to the study of economic institutions and processes, could be fitted, in Mitchell's view. Most of the orthodox theories, for example, would fit into such a scheme as studies of the logic of pecuniary institutions.

dissecting and undercutting pretentious systems of thought. But his mind was not essentially that of the skeptic, and particularly not that of the mocking skeptic. Having no pretense himself, he could be scornful of pretentiousness. But there was no scorn for honest endeavor, whether successful or not.

Mitchell found deep satisfaction in his home life. He and his wife shared an interest in education, and sponsored one of the most fruitful of the experiments that helped to break the education of the young out of the molds of nineteenth-century custom. He joyed in the companionship of his children. In their New York home and at Huckleberry Rocks, in Vermont, there was a healthy, wholesome family atmosphere. The children were partners of the parents in the life of the Mitchell household. At Huckleberry Rocks, too, there was a workshop to warm the heart of one who respected the arts of woodworking. Here Mitchell could indulge to the full his love of fine craftsmanship. He was as skilled and honest in the tasks of cutting, sawing and fitting a delicate piece of inlay work as he was in assembling economic observations and fitting them into a meaningful structure. Here, also, was his study, with contents ranging from scholarly tomes and slim books of verse to the latest detective fiction, of which contrivances Mitchell was a connoisseur. In this home, in its activities and interests, its responsibilities and its joys, there were wells of contentment for Mitchell. Here were some of the deep sources of his strength.

Wesley Mitchell's life was a full life and he was, in truth, a whole man. He found in life the abiding satisfactions that go with integrity of mind, generosity of spirit, and service to a cause that can draw man out of himself and beyond himself. In his life's work Mitchell served the human race. In his own being he helped to give dignity to that race.

FREDERICK C. MILLS

New York, N.Y.

Harry Alvin Millis 1873-1948

In the opinion of most who knew him personally and of the many more who knew him through his work alone, Harry A. Millis was a man of great and uncommon wisdom. He was a distinguished scholar, a skillful administrator, a creative and judicious arbitrator, and, without peer, a builder of men. Through his teaching, his scholarship, his decisions as an arbitrator, as a quasi-judicial official, as an administrator and an adviser on important matters of national economic policy, he exerted a healthy influence upon the lives of men and women in all branches of his society. Union leaders, company officials, workers in clothing plants, auto plants, print shops, workers in government, lawyers, university professors, students—all looked upon him with respect and admiration—and many with deep affection. In the field of industrial relations Millis will probably go down in history as the person, of his time, with the greatest number of friends and fewest enemies.

Those who knew and worked with him will probably never forget him—the way he looked, his voice, his laugh and the things he said. He was a big man—over six feet tall and his bearing was that of the athlete he was in his youth. When he walked, he walked slowly, looking neither to the right nor to the left, and as one recalls, he seemed forbidding, impressive and remote. To a few he was “Hank”; to most (and not always behind his back) he was “Pop”; to others, affectionately, the “Boss.” He could be firm, gruff, and on rare and merited occasions angry; but he was gentle, humorous, and an incorrigible sentimentalist, his grumbling resistance to the contrary notwithstanding. He loved a good story and a pointed anecdote, and his own were pungent and Hoosier-flavored. “Kid stories” featuring his grandchildren were worth repeating and remembering. He was always a great sports enthusiast, a lover of games, and a college football fan. Even toward the last, he and his grandson, “young Harry,” spent long minutes of hospital visiting time debating the relative merits of major league ball players.

It was a familiar sight at Chicago to see his students lining up outside his door after those eight o'clock classes that began his long days, as they came for advice or to report progress. No matter where his office, or how impressive the appointments, those who knew him will remember the characteristic corner of it which he inhabited, the great robust figure surrounded by clouds of pipe-smoke and high jumbled piles of books and manuscript, press releases, and miscellaneous publications that encroached upon his work-space. They will remember the twinkle of the brown eyes, the gruff manner and the slow reassuring smile. They can still see the long, large, tapered fingers and how they would reach in the vest pocket for a match, strike it under the center desk drawer, and as it flared, bring it up to the insatiable pipe. Some said he smoked matches instead of tobacco. They will remember how the smoke from the puffing pipe would become thicker and how the match would be waved out and then flung in the general direction of the waste basket, to land, with most of its fellows, on the floor. They may remember some of his favorite expressions—“meaningful,” “stout” which he insisted was better than “staunch,” “awfully,” and the sharp quick “yes!” when he agreed enthusiastically with a point made; and they may remember some of his favorite and most revealing compliments—“all wool and a yard wide,” “a horse for work,” and “clean as a hound’s tooth.”

Millis received his undergraduate degree at the University of Indiana in 1895, his M.A. in 1896, and took his doctorate at the University of Chicago in 1899. From 1902 to 1916 he taught at Arkansas, Stanford, and Kansas Universities and then in 1916 joined the faculty of the University of Chicago. In 1928, he became chairman of the economics department and held this position until he retired from the faculty in 1938. He was president of the American Economic Association in 1934-35, director of the National Bureau of Economic Research, and a founder and director of the Agricultural Economics Foundation.

During most of his academic career he was engaged in some kind of public service. He participated in the U. S. Immigration Commission’s study on *Immigrants in Industry*, published in 1911, and directed a study of

health insurance for the State of Illinois in 1917. From 1919 to 1921 he was chairman of the Trade Board of the Chicago Men's Clothing Industry and from 1921 to 1923 and 1937 to 1940, chairman of the Board of Arbitration. Of this work Mr. Potofsky, president of the Amalgamated Clothing Workers once wrote, he "helped take the clothing industry out of the sweatshops and the industrial jungle." He was a member of the first National Labor Relations Board from 1934 to 1935 and was appointed by the President to several fact-finding boards on railway labor disputes. He was also appointed by Governor Horner of Illinois to be a member of the Illinois Commission on Unemployment. He made his influence felt in the writing and development of the National Labor Relations Act and the Social Security Act and in setting up the framework for the National War Labor Board.

In 1940, sources close to the White House urged him, in the President's name, to accept a position as umpire under the General Motors-UAW, CIO agreement. Since this was the first permanent umpire set-up in the newly organized mass production industries, it was extremely important that it be filled by the best man available. It was a position requiring scrupulous honesty, delicacy, tact, and the creative imagination to lay the groundwork for sound future relations. Millis held this position only a few months, but the groundwork was laid; today officials of the corporation and the union still speak of his wisdom and his fairness. He charted not only the future of relationships at General Motors but made arbitration respectable in mass production industries generally, and set the pattern for other companies and industries.

He had been umpire for only a few months when the President called him again, this time to become chairman of the National Labor Relations Board. More than once he said of this appointment, "I was dragged into that job by the President; I certainly was not a candidate for membership on the Board, much less the chairmanship." But his administration was marked by wisdom and fairness, as always, and when he resigned in June, 1945, because of failing health, it was from a Board whose reputation had grown through his service.

In the fall of 1945 he returned to the University of Chicago to become senior adviser to the newly formed Industrial Relations Center and to begin his analysis of the development of recent national labor policy. As co-author with one of his former students, Professor Emily Clark Brown of Vassar College, he had nearly completed a monumental volume, *From Wagner Act to Taft-Hartley: A Study of National Labor Policy and Labor Relations*¹ when he died on June 25, 1948, "with his boots on," as he had always hoped.

Although Millis is best known for his works in the field of labor, his major interest as a young man was public finance. As a contemporary of Seligman, Bullock, T. S. Adams, Hallander, and a few others who pioneered in the United States, he participated in the organization of the National Tax Association in 1907. While a young assistant professor from Leland Stanford University, he wrote a paper on "Business and Professional Taxes as Sources

¹ To be published by the University of Chicago Press in 1949.

of Local Revenue," arguing for more extensive use of such taxes as a supplement to levies on property, "so as to prevent these from becoming unduly burdensome." In the evolution of state income taxation, Simeon Leland points out, no one made a clearer diagnosis of the defects of the early laws and practices. It deserves, in Leland's opinion, a better place in the literature of state income taxes. It antedates both the work of Seligman and T. S. Adams in that field.

Even in these early years his work was practical and pioneering. At a time when scientific tax assessments were just being developed, Millis had his hand in making one, sleeves rolled up, doing, as usual, more than his share of the work. In Palo Alto, where he was then living, the general property tax was operating no more fairly than elsewhere and the tax roll was characterized by all sorts of assessment inequalities. Millis thought he could eliminate some of them. With the assistance of a local banker and building contractor, the three men rode over the city in a surrey estimating the land values and the cost of constructing the buildings in the town. The latter were reduced to the square foot or cubic basis which the contractor used in bidding for jobs. The result was a much better assessment than ever before—one substantially just as between neighbors. Rumor has it that this "revaluation" lasted for a considerable period.

Even after he transferred to "labor," Millis continued his interest in public finance. He was a keen critic of whatever he read and many students are in debt to him for suggestions from his early field.

Millis' writings are, of course, landmarks in the field of industrial relations. In a field where the rapid course of events makes writings unusually perishable, the three-volume series on the *Economics of Labor*, written in collaboration with Royal E. Montgomery of Cornell University, still constitutes the most authoritative and comprehensive analysis of modern labor economics for the period covered. The industrial studies in *How Collecting Rarefying Works*, which he planned and edited for the Twentieth Century Fund, set the pattern for a great many of the case studies now being developed in the field. His last work, on the policy implications of the Wagner and Taft-Hartley Acts, done in collaboration with Miss Brown, is in press. There is little question, however, but that it will have a profound effect on the development of future national labor policy.

His work—his scholarship and his wisdom—is undeniably preserved in his published writings, though admittedly much that is eloquent appears in his unpublished arbitrations. But it is preserved perhaps even more in the influence which his broad and humane philosophy exerted upon all who were privileged to work with him or under him, whether student, colleague, or official of management or labor.

People called him a man of sound common sense. But it was more than that. At the core of all he did was a deep pervading respect for his fellow man, a sense of responsibility, and a sense of justice. He believed he must do all he could to make individual achievement possible and to free individual capacity from the limits set by meager opportunity. He was generous, he sought to understand and he sought to help; but his rocklike sense of justice never

let personal interest, bias, or affection tilt the balance in favor of one individual or group over another.

He was a man of great humility and great modesty. He went out of his way to avoid credit, publicity, or public recognition and he recoiled from all that he felt was display—whether it was the wearing of his Phi Beta Kappa key or the periodic revision of the honors rendered him in *Who's Who*. Throughout his life he felt himself deeply indebted to his beloved, brilliant, and poetic wife whose intense sympathy and sensitivity supported his convictions and shone in his work.

He had a passion for truth, for the whole of it, and for common sense in its application to the solution of problems. As a scientist and a liberal, he was tolerant of much but never tolerant of dishonesty. He was a statesman and, as one of his colleagues once phrased it, a man “of wise judgment as to the mode by which and the rate of speed at which aspirations can be converted into attainable realities.”

He was always willing to listen with sympathy and understanding to the problems of the numerous students under his direction as well as to those in other fields of economics who came to him as chairman of the department for a friendly word and a guiding hand. Yet he never sought to pry. “*Millis*,” the saying was, “*knows you have to eat*,” (and *Millis* frequently made eating possible). He was never too busy to give encouragement to any man or woman, whether student or young instructor. He was never so heavily loaded with work that he could not talk about the department, about research, about a personal problem, an idea, or a manuscript. He was never too busy to hear delightedly of the adventures of a young researcher getting his first taste of field interviews or of discovering exciting documents in union archives. When most harassed, he had time for a story or an anecdote that a student's encounter with Victor Olander or John Fitzpatrick had brought to mind. He felt all this, and the long hours that went with it, was his teacher's duty and he loved it all.

In later years many of his students wrote to him of how he had inspired them with new courage and ambition when the future looked bleak, how he alone had given them encouragement, and how he had been an oasis of friendliness, warmth, sympathy, and understanding.

He was forever willing to place other people's worries, other people's merits, the claims of other people's scholarship ahead of his own interest and his own health. This combination of sympathy and realism—this emphasis upon the use of concrete evidence in finding the solution that would make the “wheels go round,” appears in all he did, in his instruction, his guidance of graduate students, his work in public law, even his recommendations on behalf of individuals.

In his teaching he expected his students to base their conclusions on concrete knowledge of how unions and business firms actually operated. Case studies of labor relations in particular industries and detailed studies of the character and effect of public policies assumed, therefore, singular importance. Union leaders and employers were brought to class to talk and to be

questioned; classes were taken to attend arbitration proceedings; and students were encouraged to attend union meetings. Students were expected to become familiar with the literature (and many of his students remember the voluminous bibliographies he provided), to carry on their own investigations, and to do extensive field work so as to broaden the base of factual knowledge and to enrich their understanding of it. He never seemed to enjoy abstract or theoretical reasoning. Indeed, wherever he dealt with abstract values and relationships, he painted his design with a broad brush. And yet he paid theory his respects in his teaching and put flesh upon its bare bones by illustrations from his rich experience.

His influence as a teacher, however, extended beyond those who specialized in his chosen field. At a time when labor unions were largely suspect, his thoroughness, his dispassionate honesty, his forthright and simple presentations of both sides opened his students' eyes and left many of them with a sense of social responsibility that enriched their later lives.

This same sympathy and realism he manifested as chairman of the economics department at the University of Chicago. At the time, some of the departments of that institution were run by their "heads" with an iron hand with little or no participation by other full professors. The opportunities for dictatorship and less than frank discussions of policies, personnel, and budget by colleagues of equal rank were numerous indeed. But under Millis, the men of full rank settled their common destinies, a factor which greatly added to the strength and prestige of the department. When men became professors, Millis handed them the budget and other documents pertaining to their collective affairs. There were no secrets, no feuds, and men dealt fairly with each other, aided by his impartial justice and sound judgment. He inspired leadership and confidence in his staff; they swore by him just as he stood up and fought for them.

His emphasis upon concrete fact and his judgment perhaps reached their maturest expression in his career as an arbitrator and as member of the first and chairman of the second NLRB. Millis was in his time perhaps the country's greatest arbitrator. He impressed both management and labor with his scrupulous fairness, his incorruptibility, and his ability to make a decision that would work. He made his decisions, he would say, like Bill Klem, the famous baseball umpire, "I calls 'em as I sees 'em." He believed that the arbitrator must direct his efforts to working himself out of a job. The greater the number of cases a permanent arbitrator was called upon to decide, the poorer, Millis felt, the arbitrator was. Millis believed that collective bargaining was designed to establish a rule of law in industrial relations and that an arbitrator or impartial chairman was useful, especially at the beginning, to help clarify the law and make plain the way it operated. And all his efforts were directed to having the men and women in industry settle their disputes themselves, once the law was plain, by following it, rather than by resort to arbitration or to government. Yet he never made his rulings or discussed his cases in terms of abstract rights or prerogatives either of management or of the union. He dealt always with the facts and specific issues in each

case and, at some stage of the proceedings, could usually be found in the plant, inspecting the machinery and talking with those who operated it. By analysing and developing the facts carefully and relating them to the provisions of the agreement or the law, he avoided futile debates about prerogatives and, as a result, was successful in developing, on the part of both sides an understanding of what they had to do if they wanted to get along together.

In later years, when he was arbitrator in the Chicago clothing market, he had an understanding that he did not have to decide a case if he thought the people could settle it for themselves. One of many such cases involved the discharge of a cutter in one of the clothing plants. Millis thought there were plenty of precedents by which this case could be settled and refused to take it. When representatives of the management and of the union came to see him, he told them that the manager of the company involved and the responsible official of the union both knew the agreement and the precedents and both knew what to do in a case of this kind. Accordingly, he sent the representatives back to tell the manager and the union official to settle the case according to their own knowledge. They did just that and the case never came back to him for decision.

The cooperative labor relations which he stimulated wherever he arbitrated had their roots in two fundamental principles. Millis believed that unions must have sufficient power to meet their responsibilities under collective agreements. In his arbitration cases, therefore, he worked to strengthen unions in this respect and made plain to employers that such was his intention. He believed also that employers must have sufficient flexibility to handle their affairs and enough power to get their work done efficiently without undue interference from the union or from the workers. He was a stickler for the management's being able to get its work done efficiently and being able to get the quantity and quality of work to which it was entitled.

In recent years he was disturbed by the trend towards high arbitration fees. He always remembered that half of the arbitrator's fee or salary came from working people, whose earnings were meager. When he agreed to become the umpire for the UAW, CIO and the General Motors Corporation under the terms of their collective agreement, he was offered, and refused, a large salary. He explained that he wanted only enough to live on, which was about what he had been earning at the University.

His service at the NLRB from 1940 on was perhaps his most trying and demanding, and yet it seems very likely that it was the crowning achievement of his career. It was his opportunity to administer an act which to him was the "foundation for much that is helpful in our civilization as it develops." He felt intensely that the act housed "values to our nation in economic, social and communal terms"—not only in better wages, hours and working conditions, but reduced turnover, increased stability, job security, and above and beyond all this, "industrial democracy or real representative government."

On his retirement from the Board in 1945 he intended to develop more fully and document these views on the significance of the Wagner Act. The

passage of the Taft-Hartley Act the next year intensified and broadened his purpose. In his last research with Miss Brown, he sought, therefore, to bring all his rich experience to bear on an analysis and creative criticism of our national labor policy.

Here again, in this last work, and perhaps more explicitly than ever, appear those concepts and that philosophy which had colored all his work though the years. Here he stated his belief in the importance of "responsible self-government in industry" as the "main, continuous, and needed support of responsible, intelligent, representative government in the body politic."

Here he emphasized again that the plant, rather than the court, was the place where most problems could best be solved, for "industrial relations have to do with problems involved in living and working together." He looked upon the solution of labor disputes much as one would look upon the solution of marital ones. Just as the divorce court appears only in extreme instances in the solution of marital difficulties, so too, Millis writes, should litigation appear only rarely in the solution of industrial disputes. "Losses in court fights in the field of industrial relations," he wrote, "may not, indeed frequently do not, end with the close of the suit."

Believing deeply as he did in the fundamental honesty and fairness of human beings, he sought for conditions which would promote these values. His experience in arbitration and at the NLRB had yielded ample instances of deficient responsibility among union officials and members and among employers. "On the other hand," he wrote, "most experienced men have a sense of fairness when they come to know the facts. The problem is how to make a sense of fairness and responsibility more general. What will assist in effectuating, and what will militate against, this end?"

And in spite of his discouragement over ~~some of the~~ ^{governmental} labor policy, his last work reflects his continuing confidence that something could be done about difficult problems "without the effort necessarily begetting problems which outweigh the good effected." He spoke of his conviction "that cooperative thought and action on problems by those most directly concerned with them can accomplish much." Concretely, he thought that some of the difficult and controversial issues dealt with in the Taft-Hartley Act could have been, and should still be, worked out in conference under government auspices by the representatives of employers and labor and the public. Then government could play its proper role of providing the conditions under which the parties in industry could and would, in all but very exceptional cases, solve their own problems by democratic means, with due regard for the public interest.

He would doubtless have been encouraged by the startling redirection of national labor policy which occurred after his death. It is unfortunate, to say the least, that the country could not have benefited by his wisdom in that policy's formulation. Yet surely much that is good in it bears the imprint of his philosophy. And surely not a little of the hope for healthy relations in industry, for honest and creative bargaining, for wisdom and justice in administration, and for honest and creative scholarship, has its basis in his

influence. For the Millis wisdom has taken deep root in industry, in scholarship, and in the minds of those who draft our national policy. And its wholesome and humane effect will persist in men and women—in those who knew him and those who were affected by him—over the years.

BOOK REVIEWS

Economic Theory; General Economics

Économie et Intérêt: Exposition Nouvelle des Problèmes Fondamentaux Relatifs au Rôle Économique du Taux de l'Intérêt et de Leurs Solutions. By M. ALLAIS. (Paris: Imprimerie Nationale. 1946. Pp. 800.)

The author of *Économie et Intérêt*, M. Allais, is professor of general economics at the National School of Mines in Paris, and of economic theory at the Statistical Institute of the University of Paris. He is also chief engineer of the Corps des Mines.

His book is at once a piece of research, a textbook and a tract on social and economic policy. One of its distinctive features is its abstract and mathematical character. Although basic calculus is sufficient for the argument in most of the main text, a somewhat more elaborate but standard equipment is required for the argument in the technical appendices, which comprise 140 pages.

The outstanding weakness of this work arises from the fact that the author is not well acquainted with the Anglo-Saxon and Scandinavian literature. Notwithstanding the fact that much of his thinking is based on the writings of Irving Fisher, the only other modern Anglo-Saxon economists with whose work he is acquainted are J. M. Keynes and J. E. Meade. (There is also a reference to one article by J. R. Hicks.) There is no reference to Knut Wicksell's work, despite the fact that the author's cycle theory is almost identical to that of Wicksell. The implications of this limitation are obvious. The author has missed the basic modern contributions to the theory of interest, with the exception of the work of Keynes. Only too often he arrives independently at conclusions which for a long time have been part of the stock-in-trade in English-speaking or Scandinavian countries.

Following a long introduction which deals with basic concepts, definitions, and the mathematics of compounding and discounting, the author presents what amounts to a theory of interest rate determination in a real, stationary economy. In this basic economic model, money exists only as a unit of account, not as a medium of exchange. Credit transactions and even banks are present, but there is no circulating money. This construction enables him to introduce money into the picture, but to eliminate its "disturbing" effects. In such an economy investment and savings are functions of the rate of interest, and determine between them its equilibrium level. The conclusion is obvious, but the analysis leading to it is elegant and interesting.

Having completed the study of interest rate determination in a real, stationary economy, the author plunges into welfare economics. His two chapters on "Interest and Social Return" and "Interest and Social Productivity" constitute the foundation for his policy recommendations. It is unfortunate that here again the author does not seem to be acquainted with important contributions. Pareto and J. E. Meade seem to be his only sources. There is no

mention of Barone, Pigou, Hotelling, or A. Bergson. This omission turns out to be particularly serious, since his fundamental conclusion, that social product is a maximum when the rate of interest is zero, is ill-founded. Following Pareto's concepts he argues that social revenue is maximized under perfectly competitive conditions. This optimum position is not unique. The optimum points constitute a manifold infinity of values, corresponding to alternative distributions of income among individuals. He proceeds, then, to extend the proposition to the case of a dynamic but stationary economy. He argues that the time-shape of consumer expenditures is arbitrary from a welfare point of view. Individuals maximize their welfare with reference to a single point of time. Notwithstanding the fact that they take into account future satisfactions, they evaluate them with reference to the present. It can be seen, therefore, that in the general case (which includes both static and dynamic stationary states) the optimum points constitute a manifold infinity of values, corresponding to alternative distributions of income among individuals and to alternative time-shapes of consumption. For any given distribution of income and time-shape of consumption, perfect competition is optimal. His modification of Pareto's argument is merely an expression of his view that, although individuals are capable of making correct decisions in allocating their expenditures among competing goods and services in the present, they are incapable of making correct decisions with respect to saving. This conclusion is essential to the author, since it paves the way for his policy proposal that capital formation be determined by responsible government action rather than by free choice.

Next the author takes up the problem of optimum capital formation. Among all the stationary economies which satisfy the conditions of maximum social product, but the capital equipment of which is variable, there exists only one which satisfies the conditions of optimum capitalistic structure. Social product may be said to be a maximum only in this case of optimum capitalistic structure. This *maximum maximorum* obtains only when the rate of interest (in the production sector) is equal to zero. The author's proof of this proposition is not satisfactory. By treating units of factor services of the same kind, but performed at different periods of time, as homogeneous and interchangeable, he arrives at the conclusion that the presence of a positive or negative rate of discount prevents optimum allocation (which calls for equality of marginal products in different uses). A correct, generalized statement of the conditions of maximum product would have led to the conclusion that no single rate of interest is implied.¹ This position of the author is particularly unfortunate, since a great part of his policy platform is based on the assumption of the desirability of a zero rate of interest in the production sector.

The analytical climax and anticlimax of the book is reached in Chapter VIII where the author introduces circulating money into the picture. The performance of the author in this chapter is impressive, although uneven.

¹ See Paul Samuelson, *Foundations of Economic Analysis* (Cambridge, Harvard University Press, 1947), p. 233, note.

The demand for cash-balances is very aptly introduced into a model of economic unit behavior. The analysis runs essentially in terms of liquidity preference along Keynesian lines.² The author arrives at an integration of the savings-investment with the liquidity-preference theories of interest along lines which are generally parallel to the loanable fund theory. His construction, however, is entirely independent of the contribution of the Swedish school or that of D. H. Robertson, with which he does not seem to be acquainted.

The transition from the "unit of account" economy to a true monetary economy is not made abruptly but by successive approximations. The equilibrium and stability conditions of a monetary economy, in which demand for speculative cash-balances and money creation by the banking system are absent, are formulated first. For this type of economy, and as a first approximation, the rate of interest may be thought of as being determined by the propensities to invest and save, the price level being determined by the volume of cash-balances desired at this rate of interest. Monetary equilibrium is essentially defined in terms of the equality between the "pure" money rate and the "pure" claims' rate of interest. This equilibrium is stable. Any deviation from it generates forces that equalize the two rates.

Finally, the author turns to the case of a monetary economy in which both demand for speculative cash-balances and money creation by the banking system are present. This is the acid test of the book. The reader has gone through 360 pages concerning all types of simplified economies, and at long last he is ready to follow the author through the labyrinths of a full-bodied, down-to-earth economy. Unfortunately the author fails to lead through these labyrinths; he merely by-passes them. This is the anticlimax of the whole performance. The author argues that equilibrium conditions are roughly identical to those of the 100 per cent money, no-speculative-cash-balances economy. But equilibrium here is unstable. Any difference between the money and claims' pure rates of interest starts a cumulative process away from equilibrium, which comes to an end, in either direction, for reasons similar to those advanced by Wicksell in his *Geldzins und Güterpreise*. The analysis of the dynamics of disequilibrium is highly unsatisfactory. The author suddenly becomes a "literary" economist and is satisfied with vague generalities about a process which his technique is incapable of depicting. His micro-economics does not furnish him with tools adequate to deal with issues which even a simplified macro-static or macro-dynamic model could easily handle.

The upshot of the author's analysis is that money creation by the banking system and speculative cash-balances (thesaurization) are the determining causes of the instability and the cyclical behavior of our economic system. The implications for economic policy are obvious. Hundred per cent money and elimination of speculative cash-balances will stabilize our economy and eliminate cyclical fluctuations.

The final part of the manuscript deals with policy. The major objectives

² It must be stated emphatically, however, that liquidity preference is the only tool taken over from Keynes' *General Theory*.

are maximum social revenue and product and price stability. These objectives can be accomplished, the author argues, by *competitive planning*. Such planning would deal with structure rather than behavior, behavior being coordinated through the price system in a perfectly competitive economy. This structural planning involves at least the following measures: (a) a curb on monopolies; (b) a zero rate of interest in the production sector; (c) 100 per cent money; (d) elimination of the demand for speculative cash-balances.

Concerning the first item, the "competitization" of the economy, the author is very vague. In fact he does not deal with it. Here again he seems to be unacquainted with the contributions of Oscar Lange and Abba Lerner. Concerning the zero rate of interest in the production sector, as well as the elimination of the demand for speculative cash-balances, he has some definite proposals to make. The rate of interest cannot become zero unless land is collectivized, since land-values become infinitely great as the rate of interest approaches zero. But this is not all, because, in so far as the unit of account is also circulating money, the demand for cash-balances becomes very great if not infinitely great as the rate of interest approaches zero. Not only must we collectivize land, then, but we must also curb the demand for idle cash-balances. This can be accomplished by a continuous devaluation of the value of circulating money in terms of a stable unit of account. A separation of the two functions of money is a prerequisite for the simultaneous achievement of price stability, a zero rate of interest, and the elimination of speculative cash-balances. It still is possible, of course, that spontaneous saving may not be sufficient to bring the rate of interest down to zero. The government can correct this by appropriate action, which may take the form of incentives or taxation.

This air-tight, no-interest, no-profit, 100 per cent-money, perfectly competitive economy constitutes the author's policy goal. One cannot help having an uneasy feeling that the author is developing a policy for a never-never land that has few if any similarities to the world around us. The author shows very little understanding of the forces and the mechanism of economic development. He makes a fetish of stability, and has taken extreme pains to build a strait jacket for an economy that does not fit his views.

The author's contribution to the theory of interest would be significant were it not for the fact that most of his results have been available in acceptable form for some time now. It is a pity that M. Allais has worked so hard to arrive independently at some conclusions already well established. In fairness to him, it must be recognized that he has attempted a task of great magnitude, and that he has handled it with unusual skill.

A. G. PAPANDREOU

University of Minnesota

Economic Analysis. By KENNETH E. BOULDING. Rev. ed. (New York: Harper. 1948. Pp. xxvi, 884. \$5.00.)

In reviewing the second edition of a book as well known as Professor Boulding's *Economic Analysis*, the reviewer must confine himself to discussing what is new in the new edition. There are few straightforward additions of

new material, however, and the main change is one of approach. In the new edition, the chapters on money, banking, and international economics of the first edition have been partly changed and partly expanded into an integrated discussion of macroeconomics. This change has necessitated a very welcome reorganization of the book, which now consists of four parts. Part 1, on Supply and Demand, consists of the first twelve chapters of the old edition with only minor changes; Part 2 contains the new approach to Macroeconomics; Part 3 on Marginal Analysis incorporates the more elementary chapters of the similarly entitled 2nd part of the first edition; while the more difficult chapters have been taken out and assembled, together with some additional material, in Part 4, called More Advanced Analysis.

Professor Boulding's handling of macroeconomics is up to his usual high standards. He begins by pointing out the limitations of partial equilibrium analysis and the need for an aggregate approach, showing that "many propositions which are true of individuals or of small groups turn out to be untrue when we are considering the system as a whole" (p. 260). He gives an excellent discussion of aggregate concepts (Chaps. 13 and 14); he shows the fundamental identity between aggregate receipts and expenditures (Chap. 15); he introduces sequence analysis to prove the possibility of underemployment equilibrium (Chap. 15); and he discusses problems of national economic policy (Chap. 19).

All this is admirably lucid and very well done; but it provides only the skeleton of macroeconomics, while other parts of the book contain quite a lot of meat. This asymmetry would not be disturbing if the main purpose of the book were to provide the tools of partial equilibrium analysis and the discussion of macroeconomics were aimed merely at showing the connection between partial and aggregate analysis. But the author quite obviously aims at a complete coverage of all fields of economics; and by the standard of his aims there is a lack of balance between his detailed partial equilibrium analysis and his "sketch of macroeconomic principles."

To some extent this is unavoidable and explained by the relatively recent emergence of macroeconomics as a subject. (The author himself, who is aware of this lack of balance, explains it in this way.) But to a large extent it is also due to Professor Boulding's insistence on discussing macroeconomics on the same high level of abstraction and general validity on which he discusses the theory of consumer's choice and the firm's production function. This lends formal elegance and neatness to the discussion; but it causes both author and reader to overlook the main advantage of aggregate analysis: our ability to say more about the behavior of a large group than about that of an individual. It is the very essence of macroeconomics that, because group behavior is more regular than the behavior of any single member of the group, we can establish statistical laws and make specific statements about a nation's reaction to a change in incomes, or prices, or liquid asset holdings, while we can make only very general statements about the individual's reaction to the same changes.

This is not brought out at all by Professor Boulding. His discussion of the multiplier concept and the consumption function is implicit and hidden in

footnotes and examples. He mentions the parallel movement of consumers' expenditure and business investment in the interwar period as the basis of the "Keynesian view"; but he does not discuss it and warns that "conclusions must not be drawn too hastily as to the nature of the causal relationships involved" (p. 404). There can be no doubt that we are very far from a complete understanding of these statistical relations and that hasty conclusions have been drawn; nevertheless, a fuller discussion of these concepts and relations, with due warning of our rudimentary knowledge of them, would have been preferable to the author's refusal to discuss any statistical law.

Most of the other changes in the book are contained in Part 4. There is a new chapter on indifference curve analysis (Chap. 34), which applies this technique to problems of taxation and the measurement of the gain from trade. The latter is expressed in terms of the buyer's and seller's surplus; and while the discussion is clear, it is not simple and makes one wonder why the author did not use the much simpler approach of superimposed indifference maps. Another important addition is a new discussion of investment in the individual firm, contained in Chapter 36. This chapter now constitutes by far the best introduction to modern capital theory known to this reviewer. It contains the essence of the controversy between the Austrians on the one hand and Wicksell, Knight and Kaldor on the other; and it should be read by every student of capital theory. The book also contains a new section on the theory of profits (in Chapter 37) and a very good new appendix on the literature of economics.

In general, the new edition is an improvement over the old; and the book remains, in the reviewer's opinion, the best text on partial equilibrium analysis at the intermediate level. Its coverage in this field is amazingly complete. It contains the best discussion of the theory of production in the English language, the only detailed discussion of the behavior of the individual worker, and the clearest statement of the fundamentals of capital theory. Owing to the omissions discussed above, the new edition is not a "Principles"; but the days of the "Principles" are probably past beyond recall. I doubt very much if today it is either feasible or desirable to deal with the whole body of economics in one volume on any but the beginner's level.

TIBOR SCITOVSKY

Stanford University

Grundlagen der Theoretischen Volkswirtschaftslehre. By HEINRICH VON STACKELBERG. (Bern: A. Francke. 1948. Pp. xvi, 368. 19.50 sw. fr.; cloth, 23.50 sw. fr.)

This is the last work of the well-known German theorist. His untimely death, at the age of 41, occurred in October of 1946 while he was visiting professor of the University of Madrid. The book, completed by the author, appeared first in Spain shortly before his death. The German manuscript was published last year in Switzerland under the editorship of Professor Valentin F. Wagner who contributed a preface to the book.

The present "Foundation of Economic Theory" is a revised and greatly enlarged edition of the former "Outline of Economic Theory." This earlier

book appeared in Germany in 1943. It practically remained unknown because almost the whole edition was destroyed in an Allied-air raid. Both books are limited to the theory of micro-economics. There is no trace of the influence of Keynes. Generous tribute is paid to the works of Eucken, Hicks and Allen, Amoroso, Chamberlin, and Triffin. Other contemporary American writers are not mentioned.

The book is carefully organized; its presentation is exceptionally clear. All important theorems are presented in their algebraic and geometric forms, usually accompanied by further explanations in small print. The literary style is appealing; sentences are relatively short. Candidates for degrees will find it worth their while to select this book as a text for their language requirement. They will not only learn the German economic vocabulary but also review modern theory for their departmental examination. For the book is written as a text for students, a bit above the level of seniors. In its logical consistency and in its mastery of the principles, the book compares favorably with the respective texts in this country, as a review of its leading ideas will indicate.

The new book is divided into six parts. Part One (pp. 1-28) describes specialization, the circular flow, Fisher's equation of exchange, and a stable price level as the framework of the static economy. Part Two (pp. 29-104) deals with the theory of production, as well as the problem of time in production. Part Three (pp. 105-60) gives the theory of the household, considering income, demand, and savings of the household as well as its reactions to changes in prices and incomes. The theory of prices constitutes Part Four (pp. 161-256). Discussion of prices under perfect competition, monopoly and oligopoly is supplemented by governmental price regulation, and auxiliary price factors, like inertia and cartels. Part Five (pp. 257-332) comprises the theory of distribution. Rents, wages and profits receive relatively less space than the theory of capital and interest. An evaluation of the role of perfect competition as the organizing principle of the modern economy concludes the book.

Contrary to tradition, the author begins his book with the theory of production of the firm. Central to his theme is the principle of diminishing returns. It is presented in its modern form of total, average, and marginal returns as well as the rate of substitution and complementarity. The principle of marginal productivity is even applied to money. Expressing the value of the marginal products, in terms of a stable money unit, the author speaks of the principle of the "weighted marginal productivity" and presents the "principle for the equalizing of the marginal returns of money." When applied to the firm, the principle of weighted marginal productivity determines the demand, the principle of marginal cost determines the supply for the factors of production. In an equilibrium situation, the price of factors of production is then equal to the values of these marginal quantities. In discussing cost, the author translates returns into cost concepts. Increasing returns indicate declining cost. The principle of diminishing returns is thus the obverse of the law of increasing marginal cost. Cost and return concept are thus correlated and both together explain the behavior of the firm in a static economy.

The revised edition brings a new chapter on the element of time in pro-

duction. Böhm-Bawerk's theory of increased productivity through the choice of more roundabout methods of production is translated into a marginal principle. Stackelberg maintains that the element of time is governed by marginal productivity, if this principle has been properly refined. Hence, the author develops his principle of diminishing marginal productivity over time. This was published in an article in 1941 and the book contains only an abbreviated version of the principle. A producer, the author assumes, has a distinct plan for each act of investment. He compensates factors according to their discounted marginal values. The producer's most favorable period of production is obtained when the percentage increase in the marginal productivity of the respective factor is proportional to the equilibrium rate of interest. The rate of interest is thus not only a measuring rod of the respective periods of production but also of the marginal productivities of factors over time.

The author examines the merits of the marginal utility and indifference theories in his discussion of the household. For him, the indifference theory has to replace the first law of Gossen because utilities are subjective; it is neither possible nor necessary to measure them. However, the second law of Gossen is accepted as a tested fact and translated into the "balance equation" of the household in which all the marginal utilities are of equal value. (In comparing the marginal rate of substitution with marginal productivity, Stackelberg suggests two new technical terms. The curves of equal returns from factors, called *isoquants* by Frisch, are given the Greek name *isophores*; the corresponding curves for products are dubbed *isotimes*). Under the heading of saving of the household, the element of time is analysed similarly to the one in production. In arranging his streams of income so as to obtain equal satisfaction in each income period, the consumer acts according to the marginal rate of substitution over time. In dividing his income between savings and consumption, the consumer is guided by the rule of the "balance equation over time." The concluding chapters in this section on income and substitution effects, following Hicks and Frisch, are noticeable for the author's attempt to incorporate the law of Engel and the Giffen paradox into the theory of income effects.

Perfect competition, single monopoly, single monopsony, and bilateral monopoly comprise the first part of the theory of prices. The cobweb theorem is presented as an extension of the competitive price, resulting from delayed reaction and long-run adjustment of producers to changes in prices. In presenting single monopoly and monopsony, the author follows mainly Amoroso. "Cournot's point" indicates equality of marginal revenue and marginal cost for the monopolist. The "purchasing curve" of the monopsonist is derived from the marginal outlay curve of sellers. (Stackelberg argues against using the term monoposony because its Greek meaning is "demand for meat"). The "curve of exploitation" is limited to the case of a price which covers little more than the variable cost of the seller. The theory of bilateral monopoly is merely a repetition of the two previous cases, in which first the monopolist and then the monopsonist is said to dominate the situation. The respective gains are called producer's or consumer's rent.

Duopoly is regarded as the simplest form of oligopoly. Four kinds of

duopoly are distinguished. When both producers are dependent upon each other, we have "Cournot's duopoly." When both producers act independently of each other, the result is "Bowley's duopoly." The two other possible reactions are called "asymmetrical duopolies." All four forms find a detailed and admirable geometric presentation. There is, however, no explicit discussion of pure oligopoly; the whole discussion of monopolistic competition—including even price discrimination and polypolistic competition—does not exceed six pages in all. Two reasons seem to explain this scanty treatment of monopolistic competition. All imperfect market forms, excluding pure monopoly and monopsony, are said to lead to an indeterminate pricing situation. This problem the author had already analyzed in his chapter on duopoly; monopolistic competition did not seem to have theoretical significance in itself. There is also a practical reason for this attitude. Product differentiation and price discrimination are either less common in Europe or are closely associated with cartels. These were regarded as a subtype of monopoly and presented in the chapter on that subject.

The economic influence of the state induced Stackelberg to two modifications of static theory. First, economic policy was considered a privilege of the government instead of being the sum total of all economic actions, whether by private or public agencies. Second, governmental price regulation is considered a part of pure theory. Consequently, he devotes a chapter to this problem. Although different in their aims, governmentally regulated prices fall under the theory of monopoly because they are set like monopoly prices. Governmental prices can be of four different types. They can either be maximum or minimum prices as well as unchanging (*Festpreis*) or target prices. Any one of these prices can be equal to the competitive price. If the former is below or above the latter, the government will have to regulate demand and/or supply—like a monopolist. The government, too, has to obtain an equilibrium in the market, either by changing the market factors or the structure of the market itself. Government prices must thus not necessarily fail but can be just as permanent and successful as cartel prices.

The theory of marginal productivity furnishes the guiding principle for the explanation of functional distribution. Most theorems developed in the theory of production are carefully applied in the chapters on rent and wages. Yet there is no theory of an independent supply of land and labor. Labor unions are not mentioned; pure competition is assumed in all distribution chapters. The extensive chapter on interest presents a modernized version of Böhm-Bawerk's propositions. Money value is kept constant consistently; the liquidity preference of holders is not mentioned. Profit is interpreted as a differential rent which is not an element of cost. Ricardo's differential rent theory is thus applied to the special gains of entrepreneurs.

The concluding part evaluates briefly the relevance of pure theory. Presented are three propositions. Perfect competition is superior to all other economic systems; the government may organize a quasi-competitive system which may be equally effective; the Soviet economy is the system of a "total profit-seeking monopoly." These attempts to interpret existing economies in terms of pure theory reveal the usual and inevitable helplessness of the micro-

economist. All kinds of comparison have been made in the past. Perfect competition has been identified with liberalism and with socialism, and it was present as an economic ideal to fascist dictators.¹ Moreover, micro-economists have called for an additional theory—such as dynamics, welfare economics, uncertainty, money and business cycles (Stackelberg's position), or macroeconomics. They all were at some time presented as the necessary link between pure theory and economic policy. Recent attempts to coordinate microeconomics and macroeconomics are hardly promising. They have revealed the fact that a comprehensive theory of macroeconomics calls for a new theory of the firm, the household, and especially of distribution. It thus seems fair to say that Stackelberg's lifework culminated in the most comprehensive German presentation of microeconomic theory. It appeared at a time when many American economists have ceased to believe in the practical relevance of microeconomics.

Grundzüge der Theoretischen Nationalökonomie. By ALFRED AMONN.
(Bern: A. Francke. 1948. Pp. 200. 11.00 sw. fr.)

This concise outline of economic theory by the senior professor of Berne University, Switzerland, presents the main principles of modern value and price theory. In his previous books, the author distinguished between pure economic theory and "the more practically oriented" theory of welfare economics. The former deals with the principles of the individualistically organized exchange economy; the latter considers the aims and means of economic welfare and is thus the necessary link between pure theory and economic policy.

The slender volume is limited to pure theory, in which case the author is more indebted to Pareto (price interdependence) than to Hicks and other contemporary writers. The book considers five problems. It begins with the general theory of prices; deals in detail with prices under conditions of joint as well as composite demand and supply; presents the theory of distribution; discusses the relationship between money and prices (quantity theory); gives finally the theory of international values and rates of exchange. The intention is to write an introduction into theory for beginners. Yet the exceptionally long sentences, and often involved sentence structure, will complicate the reading of this book by candidates for degrees in this country.

The author rejects the marginal productivity theory and claims to have come across a new theory of distribution. He emphasizes the interaction of productive factors in the process of production. This induces him to speak of capital products or labor products, according to which factor was primarily responsible for the creation of a series of goods. In an equilibrium situation there must not only be full correspondence between the prices of the productive factors and their respective products but also, it seems, between the

various quantities of productive factors and their respective products. The "new theory" is called the necessary price differentiation between productive factors and products (*Produktpreisdifferenziertheit*).

According to the author, this new theory differs in two respects from the traditional theory of marginal productivity. Although the supply price of productive factors is normally determined by their respective marginal costs, it would be incorrect to say that the value of the various factors was "determined" by their respective marginal productivities. The value of the marginal product is just one of the variables that influences output and substitution decisions. Equally important is the extent of production as well as the price ratios between factors and final products. The marginal productivity theory is thus said to engage in circular reasoning and can thus not explain satisfactorily the functional distribution of income. Moreover, the demand price for a productive factor is based upon a joint demand for various factors used simultaneously. This problem of substitutability of factors, the author implies, cannot be handled adequately by the traditional theory.

Careful reading of the chapters on rent, interest, and wages reveals essentially the "real approach" of the traditional marginal productivity theory. Emphasis upon the necessary correspondence between factor and product prices, upon the variable proportions of factors, or upon total demand and supply, does not induce the author to employ either the "isoquant" or the "aggregate" or any other mode of analysis. Instead, the prices of the various factors are discussed without stating strictly the usual limiting assumptions. This enables the author to consider such problems as negative rent, irregular shape of the supply curve of labor, or the missing inverse relationship between supply of capital and interest. The impact of these and other problems upon the tendency towards a general equilibrium is not studied. Deviations from the equilibrium position merely lead to frictional profits which are transitional in nature. In consequence, the new theory brings essentially the traditional theory of marginal productivity stated in a somewhat less familiar form.

An appendix of eighteen pages evaluating critically the last book of Stackelberg merits the attention of theoretical economists.

Economic History; National Economies

Austria from Habsburg to Hitler. By CHARLES A. GULICK. (Berkeley and Los Angeles: University of California Press. 1948. Two vols. Pp. xxiii, 1906. \$20.00.)

Professor Gulick's study is essentially an account of the policies and achievements of Austrian Social Democracy between the two world wars, and a detailed history of the events that led to the movement's violent suppression. This story has been told elsewhere, but what distinguishes *Austria from Habsburg to Hitler* is its encyclopedic character. Professor Gulick, who

spent thirteen years at his task, has combed the relevant literature with microscopic care, and adduced an incredible amount of data in support of his conclusions, which are stated vigorously throughout. The author makes no concessions to those whom he considers responsible for the suspension and termination of democratic government in Austria, and some notion of the book's flavor may be gleaned from his prefatory remark that "I have no patience with the intellectual contortionist who apparently thinks he is 'un-scientific' unless he tries to get a part of each foot on each side of every question that is faintly controversial." Professor Gulick has followed his own precepts by planting both feet firmly on the side of social democracy.

The theme of the story is the struggle waged within the rump republic of Austria, a state of doubtful economic viability and with the added handicap of a political and cultural schism between the industrial workers and the peasants, between a socialist party that professed Marxism but practiced democracy, and a clerical party that professed democracy but betrayed it in the end. The author tends to personify the conflict, and presents it in terms of the policies advocated by the leading protagonists: Otto Bauer, the brilliant scholar who attained undisputed leadership of the Social Democratic Party, and Monsignor Ignaz Seipel, the Christian Social chancellor of Austria whom Professor Gulick regards as the evil genius of the republic, a master political strategist but a "profoundly undemocratic man." The climax came in 1927, when spontaneous riots and their suppression by the government revealed weaknesses in the socialist position that had not been appreciated either by the socialists themselves or by their opponents. Thereafter, the incursions of fascism became bolder, while the socialists were increasingly on the defensive, the process ending in the tragic events of February, 1934 and the forcible dissolution of the Social Democratic Party.

The author maintains that fascism was brought to Austria not by the Germans but "by a combination of indigenous Fascists with Roman Catholic political leaders who either betrayed their one-time political principles, or who never had any to betray." These are strong charges indeed, and adherents of the old Christian Social Party are likely to take exception to them. It may be that Professor Gulick has occasionally gone too far in his criticism, and that he does not stress sufficiently the fact that the Christian Social Party included within its ranks, and among its leadership, many good democrats. Nevertheless, the evidence he adduces against the principal leaders of the Catholic party, Seipel, Dollfuss and Schuschnigg, drawn mainly from their own public utterances and writings, is very damaging, and it is difficult to escape the conclusion that all three were totalitarian in thought and in deed.

While *Austria from Habsburg to Hitler* is forbidding in bulk at first sight, the second volume, devoted almost entirely to a detailed account of the development and triumph of Austrian fascism, is of interest primarily to the specialist in central European history, and may be skipped over rapidly by the economist. An exception is Chapter XXVII, in which Professor Gulick contrasts the doctrines and the practices of Austro-Marxism, and comes to the conclusion that while the Austrian socialists thought of themselves, and

were generally regarded, as being to the left of the mainstream of European social democracy, they acted as reformists. A gradual, almost imperceptible trend to the right resulted from the day-to-day realities involved in administering the municipality of Vienna and participating in parliamentary life.¹

Professor Gulick might have made clearer a matter of which he indicated his awareness,² the fact that while the Marxist ideology provided the labor movement with a unifying force, it was by no means an unmitigated blessing. The legacy of decades of Marxian indoctrination still remains to plague continental socialism in its struggle for survival against communism.

It is the material in Volume I, however, upon which the interest of the economist will center. After what amounts to a good-sized tome on the origins of Austrian socialism, and on the turbulent events accompanying the formation of the Austrian republic, during which the socialists fought a tactically brilliant campaign to limit excessive political radicalism among the workers, Professor Gulick turns to the impressive practical achievements of the socialists in their stronghold of Vienna.

Several of the ensuing chapters are actually monographs that can be read with profit divorced from the remainder of the book. Chapter X comprises an 80-page history of Austrian social legislation, providing a useful summary of this experience. Chapter XII deals with the cooperative movement, which was important to the socialists politically as well as economically. Socialist reform of the Viennese tax system, resulting in a substantial shift of the burden of taxation from the workers to propertied groups, is discussed in Chapter XIII, where Professor Gulick considers and refutes the charges that the new system stifled private building construction, created unemployment in the luxury trades, and prevented private capital formation.

Policies in the field of taxation rendered feasible the famous public housing projects of Vienna, an elaborate system of social welfare, and ambitious educational and cultural programs. The chapters covering some of these subjects suffer from prolixity; for example, much of the material on the socialist youth organizations, on education, and on cultural work could have been compressed greatly without impairing the value of the book. One feels that Professor Gulick's admiration for the impressive apparatus of the socialist party occasionally led him to overstate the novelty and significance of its achievements.

Despite the fact that the essential core of his study is the labor movement, Professor Gulick devotes only a single chapter to the history and practices of the trade unions. The reader will search in vain for adequate discussions of collective bargaining procedures, collective agreements, working rules, and other union policies which are everywhere the vital concern of the trade unionist.

¹ It may be of interest to note that I have reached the same conclusion regarding the Norwegian Labor Party, which was usually paired with Austrian social democracy in the European political spectrum.

² *E.g.*, p. 439: "The orthodox Marxian or Englesian attitude formed a handicap which had to be overcome before the party could put its full weight into the constructive housing schemes of the city council of Vienna."

The neglect of this phase of Austrian labor history may possibly be ascribed to the author's oft-repeated view that Austrian trade unionism "was predominantly political throughout its history." He devotes a portion of his trade union chapter to a critique of Perlman's view that "manual groups . . . have had their economic attitudes basically determined by a consciousness of scarcity of opportunity," whereas middle-class intellectuals are absorbed in philosophical abstractions, leading to "a mutual divergence in labor ideology between the 'mentality' of the trade unions and the 'mentality' of the intellectuals." On the contrary, asserts Gulick, there was no real difference in outlook between the two branches of the Austrian labor movement. The trade unions, far from evincing any desire to limit themselves to the narrow economic horizons envisioned by Perlman, "came to regard parliamentary activities as the fulcrum of labor policy," and "were increasingly regarded as the economic arm of an essentially political movement."

There was much in the peculiar circumstances of Austria that justifies Professor Gulick's approach. For example, while in 1920 the Social Democratic Party had 335,000 members against 900,000 for the "free" non-Catholic trade unions, by 1930 party membership had reached 698,000, while trade union membership fell to 655,000. Thus party membership actually came to exceed trade union membership, a situation that is probably unique in the annals of western socialism. It may be that the precarious economy of Austria precluded substantial economic gains through the traditional methods of trade unionism, and that the Viennese workers came to regard "the municipal apartments, the health and recreational services, and the reformed schools of the Socialist administration" as the chief source of increased real income.

Nevertheless, there were trade unions, and they were not entirely absorbed with politics. Some of the things that Professor Gulick himself comments upon indicate that the Perlman thesis, perhaps overstated as a general theory, does contain an important element of truth in its emphasis upon job consciousness. For example, the repeated and largely unsuccessful attempts to reorganize the Austrian federation of labor along industrial lines (pp. 272-90), attest to the continued strength of craft separatism, in the face of the class consciousness preached by the socialists. The author seems to think that the apparent trade union interest in the problem of structure was not fundamental, for he remarks that "when the primate of the party was established, the trade-union wing, as modern psychology would style it, almost 'fled' into reorganization." Moreover, he appears to attribute the conflicts over industrial unionism, as well as the persistence of jurisdictional disputes, to "oligarchic tendencies [which] unavoidably arise even within the framework of the most democratic institutions." Yet at another point he records these interesting facts about the 1919 congress of the Federation: "Between the last (1913) and the present (1919) congress lay the fateful period of war and revolution; nevertheless, the report of the *Kommission* on these meaningful years was almost neglected. But when the congress turned to the question of reorganization no less than 44 individuals asked for permission to speak, and before the debate was closed 26 had expressed their views on industrial unionism."

Another illustration of differences in outlook between the party and the trade unions is afforded by the crucial issue of coalition. After leaving the government in 1920, the socialists were continually weighing the desirability of returning. By re-entering into a coalition with the Christian Social Party, they might have obtained several cabinet posts, and perhaps have averted the transformation of the army and the police, which had been radicalized after the first world war, into instruments that could be used against them. On the other hand, they would have had to share responsibility for some unpalatable economic and political decisions that were inevitable under the circumstances.

The socialists were, as Professor Gulick shows, on the horns of an almost insoluble dilemma. To remain in the government after 1920 might have strengthened the communists and impaired the unity of the labor movement. On the other hand, there were not a few within the party who agreed with Karl Renner that "the July [1927] occurrences were a consequence of the steady refusal to join a coalition government in past years. Only thus had it been possible for the opponents to transform police and army into willing tools of their policy and to arm the Heimwehr."

The trade union leadership appears to have shared Renner's views. Gulick quotes a revealing statement by a prominent trade unionist which perhaps epitomizes the divergent views of the political and economic branches of the labor movement: "We trade union men feel it on our hides that it is not a matter of indifference for the proletariat whether it is our highly respected comrade Hanusch who sits in the ministry of social administration, or a Pauer or even a Schmitz." (The latter two were non-socialist politicians, while Hanusch was a leading trade unionist.)

No one is likely to agree in every essential with the analysis and interpretations in *Austria from Habsburg to Hitler*. Nevertheless, reading this case study of democratic socialism in action affords an exciting intellectual adventure. It is far more than the history of the labor movement in a small country, for many of the problems treated are relevant today in all of western Europe: the constant threat of communism on the left, the dangers and advantages of coalition with center groups, the relationships between party and trade unions, the quest for an ideology suited to present realities. I hope that Professor Gulick's important work will receive the wide attention that it merits.

WALTER GALENSON

Harvard University

The Brazilian Economy. By HENRY WILLIAM SPIEGEL. (Philadelphia: Blakiston Co. 1949. Pp. xv, 238. \$4.50.)

This is a very valuable contribution to the growing literature on the economic problems of the other American republics. It is only in the last few years that any number of American scholars have turned their attention to the nations to the South and problems which they have to face. The works of Wyeth and Hughlett on the industrialization of Latin American were among the first studies of this kind, while the work of Ellsworth on Chile was one of the first attempts to tackle the problems facing one particular

country. The present work by Dr. Spiegel, who is an associate professor of economics at the Catholic University of America, is a welcome addition to this field.

Some of the difficulties of those who attempt to deal with the economic problems of the Latin American region are evidenced in Dr. Spiegel's work. With regard to most subjects with which the author deals, the statistical material is very sketchy. Dr. Spiegel does a valuable job in trying to assess the value of the available data, and to use them to get a general picture of the economy of the nation. However, as he indicates, about the only area in which statistical material is at all adequate is that of foreign trade. Because of the importance of taxes on imports and exports as a source of revenue for the government of Brazil, it has for many years kept quite accurate figures in this field.

In such fields as population, labor, agricultural production, national income, and cost of living, the material available for the economics student varies from not so good to nothing at all. And what is true of Brazil is true to a greater or lesser degree of most of the other Latin American nations. Perhaps Argentina, Chile and one or two other countries would rate a bit better in the quality of economic data available, but for the most part the Latin Americans have not been particularly interested in the collection and correlation of economic statistics.

Dr. Spiegel's book is notable for reasons other than the fact that it is a pioneer in the field. It is notable because it attempts to apply the national income approach to a comparatively "backward" nation. Indeed, he starts out his study with a chapter on the national income, indicating the distribution of income payments to various elements in the community, and discussing the problems of savings and investment in a country in which the great majority of the people have very small incomes.

The author then goes on to deal with what is perhaps the outstanding characteristic of the Brazilian economy, the fact that for more than one hundred years the country has been experiencing a virtually uninterrupted inflation. Dr. Spiegel concludes that this inflationary spiral was brought about in large part by the very large volume of exports, which resulted in the release in Brazil of a large quantity of money for which there was comparatively little offset in domestic production. At the same time, he notes that until the first World War, at least, these very large exports merely served to pay for the equally large imports of capital.

This long-range Brazilian inflation has generally been accompanied, according to Dr. Spiegel, by budget deficits and currency depreciation in addition to the export surpluses and inflow of capital which we have already noted. Since 1942, however, the trend towards currency depreciation has been halted, though prices have gone up even more rapidly than before. This is in large part due to the fact that exports are influenced more by the lack of domestic mass purchasing power than by the requirements of the balance of payments.

Dr. Spiegel feels that the fundamental necessity in Brazil is to increase the productivity of its agriculture and industry. This has been held back heretofore by the cheapness of labor. The author maintains that Brazilian

labor is still cheaper than that of the United States and other industrial nations, even when the very much lower productivity of the Brazilian worker is considered. He notes, however, that the power of the workers' organizations is growing and that labor costs are therefore rising, and he believes that sooner or later that tendency will make it necessary for Brazilian employers to introduce more machines and more efficient machines than have hitherto characterized Brazilian industry. He notes that in the textile industry this tendency is apparently already under way.

Industrialization is the principal method upon which Brazil must rely in the years just ahead, according to Dr. Spiegel. He discusses at some length the problems involved in industrialization, such as a small market, difficult transportation, scanty capital resources. In this connection, one misses a more adequate discussion of some of the labor problems facing the new manufacturing industries. He feels that much of the capital for the development of industry in Brazil must come from abroad. He notes that there was a strong emphasis on economic nationalism between the two wars, but that since World War Two restrictions on foreign capital have tended to be relaxed. He believes, however, that, though the Brazilians will tend to welcome foreign capital, particularly in manufacturing enterprises, it will have to come to Brazil on more equitable terms than were customary in the earlier era.

Dr. Spiegel also believes, on the basis of the evidence which he presents, that the Brazilian government will itself play a large part in this industrialization process. Not only will it extend the customary kinds of aid to infant industries—tariffs, tax reductions, subsidies—but the government itself will establish or help to establish many of these industries. He notes five such heavy industrial enterprises in which the government has been the prime mover during the last decade, and feels that this trend will continue. This, as Dr. Spiegel points out, is quite consistent with the tradition of economic behavior in Brazil, where the ideas of *laissez faire* never had more than fleeting popularity.

In addition to these problems directly concerned with the growth of manufacturing, Dr. Spiegel devotes his attention to the agriculture and transportation of the country, noting the difficulties of the latter, and noting the changing nature of the former—the decline of the old staple crops of coffee, cotton and sugar, and the growing tendency towards diversification of agricultural production. He feels that the trend during the next generation will be towards more emphasis on food crops for consumption within Brazil, and less emphasis on the great export crops.

This volume is a trail blazer in its field. It is a very readable and very useful work not only for those particularly interested in Latin American affairs, but for anyone who is interested in the basic problem of the development of "backward" countries. And, if President Truman's inaugural address is any indication, this is a problem in which Americans will become increasingly interested.

ROBERT J. ALEXANDER

Rutgers University

Studies in the Development of Capitalism. By MAURICE DOBB. Rev. ed. (New York: International Publishers. 1948. Pp. ix, 396. \$3.50.)

Maurice Dobb, lecturer in economics at the University of Cambridge, is best known for his studies of Soviet economy and his criticism in avowedly Marxian terms of current economic theory. In turning to economic history, he steps out of his customary role and addresses a subject in which he is not a specialist and for which he relies upon the findings of the more prominent workers in the vineyard. In his endeavor he retains his refreshingly frank Marxian position and views history from that particular vantage point.

Being, apparently, a fearless intellectual, Professor Dobb attacks at once one of the most bothersome points of his subject—the term capitalism. He will have none of Sombart's vagueness, which regards the institution as a *Zeitgeist*, or of the German historical school's attempt to identify capitalism with money economy. He lines up with Marx in the belief that what distinguishes capitalism most particularly and sets the period of capitalism off most distinctly from other periods of history is that under it workers were deprived of the means of production, that these means were owned by investors, and that workers were thereby exploited by their employers. Basic to this entire presentation is the labor theory of value.

This fundamental proposition conditions the things Dobb looks for in the development of capitalism. How, when, and why did workers lose the means of production; how, when, and why was ownership acquired by an employing class; how has the employing class used its economic and political power to maximize benefits to itself; and what have been the recent trends within the institution which may be projected into the future?

These concerns have led Dobb to throw overboard such categories as "merchant capitalism" and the Sombartian stages in capitalism. He adopts stages which are determined by the growth of the dispossessed, industrial proletariat. In his view the crucial turning points in England were the end of the "sixteenth century and the beginning of the seventeenth when capital began to penetrate production on a considerable scale" (p. 18) and in the late eighteenth and early nineteenth centuries with the industrial revolution. The Bourgeois got control of the means of production not primarily by accumulating capital out of income, but by taking advantage of shifting price differentials between types of property.

The ownership-of-the-means-of-production class has used its economic position to get political power and has sought legislation to give it monopolistic positions and control over labor. Mercantilism, for example, is regarded as a system of "state-regulated exploitation through trade. . . ." "State intervention tended to grow in countries of Western Europe in the fourteenth and early fifteenth century, which was a period of almost labor scarcity, and again in the seventeenth century, which was in France, for example, the age of Sully, Laffemas, and Colbert; whereas the nineteenth century, a period of abundant labor reserve and rapid increase in population, witnessed the greatest triumphs of *laissez faire*." By the twentieth century, capitalism had reached a point where there was a "chronic fear of increase of products and productive capacity," "an arresting of technical development," and a threat of a collapse of the entire capitalist system.

Dobb has a neatly organized account, but he has imposed great limitations on it through his emphasis upon the labor theory of value. Surplus value undoubtedly arises from various factors of production and not from labor alone, at least, the historical record indicates that this is so. Hence capitalism as an institution has many facets which Dobb has largely ignored. Furthermore, he gives away a part of his case regarding labor theory of value as the distinct aspect of capitalism by stating that under feudalism, that is, before capitalism, the wealth of the lords resulted from surplus labor of serfs. Finally, what freshness and light there may be in the book are obscured by a wordy and turgid text.

SHEPARD B. CLOUGH

Columbia University

Russia in Flux. By SIR JOHN MAYNARD. Edited and abridged by S. Haden Guest. (New York: Macmillan, 1948. Pp. xviii, 564. \$6.50.)

The late Sir John Maynard wrote about Russia with an unusual perspective gained from a long career in another backward country, India, and with an authority derived from several visits (including one as early as 1895-96), as well as from independent study. This volume combines in abridged form two collections of essays previously published in England: *Russia in Flux before October* (London, 1941), and *The Russian Peasant: and Other Studies* (London, 1942). Running over virtually the whole range of Russian and Soviet life and history, the essays inevitably are rather uneven in quality. Unquestionably, however, some are first-rate contributions and the viewpoints expressed are interesting throughout. No student of Russia will wish to pass this work by.

Among the different essays, numbering twenty-seven in all, four discuss the currents of political, social and religious thought in Russia in the three-quarters of a century before the Revolution. These are probably among the most valuable in the volume. Maynard apparently did a prodigious amount of reading in Russian sources, and he manages to present in a brief space what seems to be a most comprehensive catalogue of the main intellectual figures and their thought, including, to mention only a few, the slavophile Khomiakov, the westernizer Chernyshevsky, Bakunin, the populist Mikhkailovsky, Tolstoy, Plekhanov, Struve and, of course, Lenin. The discussion is monographic in character and does not seem to focus on any particular thesis.

All of six essays deal with agriculture, including particularly Tsarist peasant living conditions, the organization of the Mir (which it is not generally realized was still, on the eve of collectivization; the dominant factor in Russian agricultural organization); the twists and turns in Soviet agricultural policy since the Revolution; the collectivization drive and the organization of the collective farm. These materials will be of interest both for the information assembled, though little seems distinctly new, and the interpretative comments, which are always challenging. While Maynard may tend to understate the initial peasant opposition to collectivization (p. 267), and at the same time overstate the mass support that has since been won for the new form of agricultural organization (Chap. XX), he is probably right in pointing to the war experience as indicating rank-and-file peasant loyalty

to the regime. In the light of the unrest during the collectivization drive many foreign observers were led to believe that the Soviet government might not be able to count on the peasantry in a national emergency. On the basis of his own travels in the Ukraine and North Caucasus in 1932-33, Maynard questions that there was anything like the severe famine there, leading to millions of deaths, such as many commentators reported at the time (pp. 249-50).

The materials on the evolution of Soviet agricultural policy should be read in conjunction with an all too brief essay on the controversies within the party in the 'twenties. Agricultural policy was one of the principal issues in these debates, and Maynard presents a very summary survey of the views held by different groups in the party on this and other questions, including industrialization, the status of the trade unions, foreign policy and so on. As Maynard suggests, the ideological differences between Trotsky and Stalin probably were not nearly as clear-cut as is often imagined. Certainly on economic questions, particularly agricultural organization and industrialization, Stalin at the close of the debates was at least as far to the left as Trotsky ever had been.

Unfortunately for the readers of this journal, the brief discussion of Soviet planning is altogether superficial, and will be of little interest to those familiar with any of the standard works on Soviet economics. It should be noted that, contrary to what is said (p. 341), the Soviet government was definitely interested in financing the first and subsequent five-year plans partly from foreign borrowing. Also, in view of the Labor Reserve School Act of October, 1940, to which reference is made, and certain other labor control measures instituted in the same year which are not discussed (see the reviewer's *Structure of Soviet Wages*, Cambridge, 1944, Appendix F), many probably will not share Maynard's opinion that "At all events the USSR is free from unemployment, and the choice of occupations is freer than in a country where young people must take the first job that offers, or else risk finding none" (p. 336). Except for a brief comment, no attempt is made by the author to grapple with the question of penal labor.

The balance of the essays, which space forbids us to comment on in any detail, includes several studies of a general historical character centering mainly on the three revolutions and the civil war; some studies on Soviet political institutions, which seem controversial at numerous points, particularly the purges; several essays on nationalities and religion; a summary appraisal of the living and working conditions of urban labor; a summary appraisal of recent currents in Soviet ideology, including the rôle of patriotism, attitudes toward the family, etc.; and a final and very provocative essay attempting to evaluate the Soviet system in terms of the opportunities provided for personal development.

At various points in his essays Maynard voices several familiar themes: the mass of Russians are little affected by or concerned with the vagaries of the police system, are mainly interested in security and economic and social leveling, and are probably not yet ripe for political freedom. These are, of course, all matters of opinion. Interestingly, the even more backward country

where Maynard spent his career seems now to be building its political system on quite different premises.

Unfortunately, these essays are much too loose-knit and their coverage too uneven to constitute anything like a systematic survey, suitable for textbook use. For specialists, their value is impaired by the lack of documentation. The general reader, however, will find this an unusually thoughtful and provocative book.

ABRAM BERGSON

Columbia University

Money, Banking and Credit in Mediaeval Bruges. By RAYMOND DE ROOVER.
(Cambridge: The Mediaeval Academy of America. 1948. Pp. xvii, 420.
\$8.75.)

Drawing upon a long list of monographs and published documents and interspersing fresh data from Belgian and Italian archives, Professor de Roover has produced a noteworthy synthesis of financial history in an area where capitalistic institutions were relatively mature in the fourteenth century. Some important generalizations hold for the rest of Flanders as well as for Bruges; and, since many of the city's bankers were Italians, the study also bears on Italian history and parallels in part the author's *The Medici Bank*.

Following the Belgian historian Bigwood, de Roover finds that banking embraced three distinct groups: (1) the merchant-bankers, principally Italians, who specialized in foreign exchange; (2) the lombards, whose chief business was pawnbroking; and (3) the money-changers, mainly Flemish, whose operations evolved from "petty exchange" into deposit banking. Before the end of the mediaeval period Antwerp "inherited the position of Bruges as the financial metropolis of northwestern Europe," but by the turn of the seventeenth century Amsterdam outranked Antwerp. Definite links are established between mediaeval practices and banking in Amsterdam: the public bank of Amsterdam, founded in 1609, "performed the same functions as the Bruges money-changers and should be considered as their direct descendant."

The three classes of bankers did not form "hermetically sealed" groups, but it is significant that specialization was favored both by the business community and by legislation. (Thus, the money-changers were not allowed, and apparently did not want, to compete with the lombards.) Though really doubtless formed the main type of wealth, no special market or institution catered to real-estate financing. Indeed, this aspect of credit is dismissed in a sentence: "Real estate owners could obtain credit more cheaply from institutions and private investors, interested in a steady flow of income, than from professional lenders." Public finance is similarly limited to casual statements: "Loans to public authorities . . . occasionally found favor with the lombards"; while the money-changers advanced funds to the city government "only in great emergencies." Lacking portfolios of mortgages and government securities, the money-changers made direct investments in commerce, particularly in the cloth trade; but even this was forbidden in 1477.

Money, Banking and Credit examines elaborately the problems of currency and short-term credit instruments and institutions; it answers few questions concerning long-term debt, either public or private, and the processes of capital accumulation.

In the fourth and fifth chapters de Roover reviews and expands his previous expositions of the mechanism of mediaeval exchange. Despite meticulous efforts to dispel false ideas of the subject, the discussion retains several puzzling statements. All important money markets were interrelated and arbitrage was practiced; monetary debasement as well as interest rates affected exchange rates; yet the "equilibrium of the money market required that the rate of exchange be always higher in that one of the two places which gave its currency to the other. . . . This rule is of general validity, and there are no exceptions" (p. 62). Is this an obscure way of saying that in a given market there was always a spread between the buying rate and the selling rate of a foreign currency? One hesitates to challenge an author who is sure that "on all these points [relative to foreign exchange] the demonstration given in this study is complete and decisive" (p. 353).

There are other points on which scholarly caution yields to undue speculation and assertiveness. A re-examination of the "widely current theory" that debasement "is explained by the dwindling supply of precious metals in Western Europe" leads to the conclusion that "temporary difficulties" (e.g., adverse payments balances, work stoppage at the mints) were more important than any long-run factors tending to depress the price level. Although the evidence concerning the effects of monetary policy on the price level is "admittedly scarce," the author does not hesitate to affirm that Flemish prices "rose sharply during the fourteenth century and more slowly during the latter part of the fifteenth century." Subsequently, it appears that "for the fourteenth century there are no price series or index numbers available, but other documents give a fairly good idea of what was going on." On the other hand, "it would be dangerous to make any generalizations" in the absence of price statistics; but "their importance should not be overrated."

In conclusion, the author admits his inability to answer one important question: Were there business cycles in the Middle Ages? But seasonal fluctuations in the money market were commonly recognized by the bankers of Bruges; and, "if there are seasonal fluctuations, the existence of larger waves, that is, of cyclical fluctuations may be presumed and cannot be rejected *a priori*."

ROBERT S. SMITH

Duke University

Trois Essais sur Histoire et Culture. By CHARLES MORAZÉ. (Paris: Librairie Armand Colin. 1948. Pp. 62. 90 fr.)

These three essays, by M. Morazé, lecturer in economic history at the Institut des Hautes Etudes of the Sorbonne and one of the editors of *Annales*, are of importance for their emphasis on a return of man to a position of central significance in historical and economic study. In a brief foreword, the veteran Lucien Febvre compliments Morazé because, though in no sense

a pupil of his, the younger man has strengthened his hand in his lifetime plea for a geohistory, a history not stultified by the worship of mere *fact*.

Entitled respectively "From Facts to Man," "From Number to Man," and "Order and Method," these essays study the subordination of fact to space and time in human history, the inevitable intervention of man into his own statistical determinism, and the need for a restoration of philosophy in the history of culture.

Taking a single *fact*—the appearance of Jules Ferry at the head of the French government—Morazé demonstrates how far a fact is from being an absolute, and how it is linked with apparently remote elements in geography, time, and cultural history. History thus becomes psychological, "the life of Man."

In his discussion of number, Morazé traces the rise of statistical determinism in the 19th century, and then the inconsistent effort of man to level off the curves of his own dialectic of inevitable numbers. Thus in "Order and Method," Morazé arrives at a challenge to the effort to find a universal history of humankind on a parallel with the natural sciences; and he calls for a reversal of the present hierarchy of specialists toward that "infinitely more difficult and rarer" acquisition of "broad intelligence and encyclopedic reading" which alone can restore perspective in the history of man and man's culture.

Economic Systems; Planning and Reform; Cooperation

The American Economy. By SUMNER H. SLICHTER. (New York: Alfred A. Knopf. 1948. Pp. vii, 214, ix. \$2.75.)

This book is an analysis of the American economy—its problems and prospects—as seen by a celebrated economist. Professor Slichter first sets out to examine the basic characteristics of the economy. He next explores four of the principal problems of the economy, and finally gives an appraisal of its strong points and weaknesses. By way of introduction he states that the American economy is the most productive in the world (with six per cent of the world's population and an even smaller percentage of the world's labor force, the United States produces over one-third of the world's goods). He believes that the great strength of this extraordinary economy is little appreciated by the people of the United States, and even less so by the people of other countries. The economy has great problems, and its institutions are under attack.

Professor Slichter writes:

The economy itself is undergoing a basic transformation. About fifteen years ago power began to shift rapidly from business men and the self-employed to employees, who are by far the most numerous group in the community. This shift of power is still in its early stages, but is going on rapidly. The prospects of the economy are much in dispute. Many people

believe that it has become "mature" and that it is rapidly losing the capacity to grow. Other people think that the shift of power from employer to employees will undermine the spirit of enterprise and hinder the growth of industry—that no laboristic economy can be as progressive as a capitalistic one. Still other persons are impressed with the fact that industrial research is growing by leaps and bounds, and that the industrial revolution appears still to be in the early stages of its development. They count on rapid technological change to keep the economy dynamic.

Once these issues are set forth as the subject matter of the book, Professor Slichter outlines what he believes to be five principal characteristics of the American economy: (1) The economy is predominantly one of private enterprise; (2) it is a laboristic economy; (3) it is highly competitive; (4) it is highly dynamic; (5) the economy is highly self-sufficient.

While each of these propositions is qualified and documented, one cannot let them all pass by without some challenge. Certainly one cannot accuse Professor Slichter of being a conformist; he has persistently stuck by his guns in defending his wartime position that the vast backlog of savings and deferred demands would maintain full employment during the postwar years, while many economists predicted millions of unemployed. Similarly, he is in the minority here regarding his position on competition. Most economists would probably agree that the economy has too little of the competition necessary to provide the most effective balance wheel for allocating resources into the most productive channels. While emphasizing that the American economy is highly competitive, Professor Slichter tends to give inadequate recognition to the significance of the rapid growth of corporate concentration of industry under investigation by the Antitrust Division of the Justice Department and the Federal Trade Commission. Relevant also to the monopoly question are the recent activities and revelations of the Senate Small Business Committee.

It is not difficult to accept, for the most part at least, his thesis about the economy, which he implies can be expected to become more "laboristic" over the long run. But this is also to be interpreted as meaning that strong *farmeristic* elements will be important, and merits consideration in evaluating any thesis that the economy is largely "laboristic" in nature.

Professor Slichter lists four problems which he believes stand out above all others in importance; some of these he believes are more political than economic. They are: (1) The problem of industrial relations; (2) The problem of economic stability; (3) The problem of international economic policies of the United States; (4) The problem of incentive to expand industrial capacity to increase production.

He emphasizes that the interest which the community takes in labor matters will largely determine whether management and trade unions cooperate effectively to increase output and to determine working conditions, and that it will determine in larger degree the nature of the impact of trade unionism upon the scale of values of the country. Thus, it becomes imperative that there be developed a generally accepted body of principles as a guide to settlements which are equitable and in the general welfare. Professor Slichter

believes that these principles must either be accepted by both parties or enforced by a national wage and arbitration policy. Several instruments for dealing with emergencies should be possessed by the government. He is against governmental seizure of plants. He thinks voluntary arbitration would be preferable when bargaining disintegrates. If this fails, he favors required arbitration. If one party or both reject the recommendations of an impartial emergency arbitration board chosen as neutral and competent by representatives of labor, the President (or the governor) might require both parties to try out the board's recommendations for six months or more. This prolonged "cooling off" period introduces an uncertainty which each party would wish to avoid.

While Professor Slichter's discussion of industrial relations is cogent and encompasses much admirable analysis, his section on the business cycle suffers from over-concentration. By way of stressing the role of savings and investment, he gives much attention to the need for tax revisions that would encourage more risk taking. Two steps should be taken to correct the present income-tax inequities. One is to permit income-tax receivers to pay a tax on their average income over a limited period of years; and, second, "... permit a substantial part of capital losses to be offset against general income in the year that capital losses are realized."

In his excellent chapter on international economic policy, he explains the job of ECA, the chronic shortage of dollar exchange, and the great need of the United States to import more goods.

After examining the pertinent facts Professor Slichter tries to dispel the belief that this is a "mature economy," and concludes that there are powerful forces still making it possible to have great technical progress. He lays the responsibility for this progress squarely upon the so-called "new laboristic society" that he believes is emerging. Its great challenge is to open "... the markets of the United States to the rest of the world and in developing far closer economic ties between this country and other countries." If this is done "... the standard of living should continue to double every forty years or less."

While presenting a vigorous and provocative approach to the subject, this book is at the same time a thoroughly scholarly piece of work. It deserves to be widely read and digested, particularly by all those persons interested in maintaining our American institutions.

CHARLES D. HYSON

Harvard University

Individualism and Economic Order. By FRIEDRICH A. HAYEK. (Chicago: Univ. of Chicago Press. 1948. Pp. vii, 272. \$5.00.)

The degree of civilization that mankind has yet attained, and any conceivable progress therein, has been, and will be, attained by planning. Progress in civilization has also been marked by, and is practically synonymous with, the release and development of the constructive powers of individuals and the suppression of their predatory tendencies. The task of social planning is to enable men to take joint constructive action that they cannot take as

individuals or private groups, to contract for their mutual benefit on the basis of mutual renunciation of antisocial practices, to suppress the socially vicious activities of those who will not make any such renunciation, and, for the rest, to give rein to the full and free expression of individual personality and talent in sole or collective endeavor.

Nothing, therefore, could be sillier than an attempt at serious contrast between planning and no-planning, in either the individual or social sphere, unless one is prepared to argue for improvidence, chaos, and the war of each against all, as the *summum bonum* of the human race. This is not the real choice that confronts us but rather where, what, and how much centralized planning there shall be, and how much individual responsibility. Our preference must be between the jungle and the jail, and most of us, I conceive, would like things to be about as far away from either of these extremes as from the other (unless, of course, we picture ourselves as the wardens of an incarcerated community industriously engaged in ministering to our whims). In the jungle there is, of course, no central planning while, for the inmates of a well-run jail, all individual planning, especially for escape, is either futile or damnifying to the central plan.

In *Individualism and Economic Order* Professor Hayek attacks, rather than as in his *Road to Serfdom* he seemed to me to skirt, the *essential* question. The book is a collection of previously published essays which, in some degree, attains the happy result of Simons' *Economic Policy for a Free Society* of being greatly more impressive as a whole than as a mere sum of the parts. The last two essays, however, on "The Ricardo Effect" and "The Economic Conditions of Interstate Federalism," appear to be a vermiform appendix with no function, *in this book*, other than to bring it to a size to which the publishers might attach a price tag of five dollars and still avoid the blush that must otherwise effuse even the hardened faces of their kind.

The first six essays "Individualism: True and False"; "Economics and Knowledge"; "The Facts of the Social Sciences"; "The Use of Knowledge in Society"; "The Meaning of Competition"; and "'Free' Enterprise and Competitive Order" are brilliant expositions of the general themes that, under an automatic system (that is, one that relies on the drives of individuals seeking their own ends); we build far better than we know, and that any sort of detailed central planning must, along with its lack of mobility and adjustment to kinetic conditions, inevitably lose the benefits of the immense store of dispersed special experience and information of which the social "know-how" is composed.

The three essays on Socialist Calculation (Nos. VII, VIII, and IX) conclusively argue that, in a collectivist regime, there is no possibility of optimum allocation of resources on the basis of consumers' preference, and, to this reviewer at any rate, carry the conviction that there is a negligible probability that this can be done anyway near as well as in even a far from perfect system of free enterprise. It is not so clear, however, that specific (narrow) ends may not be reasonably well attained in a collectivist system, provided free choice to the individual is a matter of little, if any, concern to the directorate. Though this was not the point at issue, one may expect from

Hayek's opponents the charge that he is comparing not ideals with ideals, or facts with facts, but the ideal theoretically obtainable through free individual enterprise with an ideal which some collectivists do not hold or with the disconcerting facts quite obvious, contumaciously denied, or shamefacedly concealed, in existing collectivistic societies.

The essential defects in such approximations to free enterprise as the world has yet seen lie in the lack of provision of a rational monetary system for a pecuniarily motivated "order" and in the consequent waves of involuntary unemployment with which all of them have heretofore been afflicted. The inclusion, as No. IX, of the essay on "A Commodity Reserve Currency" is Hayek's recognition of these defects and his prescription for their alleviation. Hayek's strong endorsement of this monetary reform should suffice to remove all suspicion of him as a reactionary (which he has, of course, never deserved) and to separate him from those who seem to believe that nothing new can be good as sharply as from those who are unaware that, if history throws a most uncertain light on what is good, it can at least suggest that what men in the past have always rejected (when, after long experience, they have had the chance) is a highly unpromising path for the present and the future.

FRANK D. GRAHAM

Princeton University

Business Fluctuations; Prices

Measuring Business Cycles. By ARTHUR F. BURNS and WESLEY C. MITCHELL.
(New York: Nat. Bureau of Econ. Research. 1946. Pp. xxvii, 560. Tables, 201. Charts, 77. \$5.00.)

This is the second volume in the series entitled "Studies in Business Cycles."¹ Impressive in scope and executed with painstaking care, the work presents a detailed, technical analysis of a method for studying the cyclical behavior of individual series. To those who place their credence in aggregative data or in composite indices of economic activity, the approach undertaken by Burns and Mitchell may appear complicated and time-consuming. But since our usual aggregative data have not, to date, adequately served either to support or to refute numerous hypotheses of economic theory, an atomistic analysis of business activities is likewise essential. As a preliminary to forthcoming monographs and to a third summary volume, the present work discusses numerous statistical tools and subjects several important causation hypotheses to valuable tests of significance.

From a detailed analysis of 1277 individual series in the United States, Great Britain, Germany, and France² and a partial analysis of many more,

¹ The first was *Business Cycles: The Problem and Its Setting*, by Wesley C. Mitchell, which the National Bureau of Economic Research published in 1927. Mitchell's earlier work, the pioneer and monumental quarto volume, *Business Cycles*, was published by the University of California, in 1913.

² Of this total, 76 per cent relate to the United States, 11 per cent to Great Britain, 7 per cent to Germany, and 6 per cent to France; the series cover production, transportation, employment, prices, inventories, sales, and monetary circulation.

the authors arrive at the following definition: "... a business cycle consists of expansions occurring at about the same time in many economic activities, followed by similarly general recessions, contractions, and revivals which merge into the expansion phase of the next cycle; this sequence of changes is recurrent but not periodic; in duration business cycles vary from more than one year to ten or twelve years; they are not divisible into shorter cycles of similar character with amplitudes approximating their own" (p. 3).

To determine the chronology of turning points in general business activity, the authors date the alternate peaks and troughs of seasonally adjusted, specific cycles occurring in each of the individual series included in the study, following the pattern of the definition just given. The series are chiefly monthly, to insure greater exactness in selecting the true turning points within years. From the consensus of turning points in these "specific cycles," the monthly dates of the "business cycle" are designated, not without qualms, but with a belief that this chronology, though approximate, is more trustworthy than any other devised to date. The turning points so selected generally harmonize with the annals of business and with the best known composite indices of business conditions in the United States.

Following the determination of business cycle durations, useful as a norm for comparison, Burns and Mitchell then introduce the statistical methods to be used by the National Bureau in the future analyses of individual series. The first set of methods involves five S (specific cycle) tables, usually based on a positive, trough to trough,³ analysis of each complete cycle within a single series.

These enumerate:

S(1) the duration in months of specific cycles during expansion, contraction, and the full cycle: and the timing difference, in months, between specific cycle turning points and corresponding business cycle turning points, *i.e.*, the enumeration of leads or lags.

S(2) the specific cycles expressed as relatives: the absolute value for each full positive cycle is divided by the average of the absolute values for the corresponding full cycle; thus the inter-cycle secular trend is removed but not the intra-cycle trend. The index for each turning point represents a three month average⁴ centered on the month containing the turning point, thereby partially eliminating the random fluctuations. Amplitudes are then derived for the expansion phase (positive difference), for the contraction phase (negative difference), and for the full trough to trough cycle (difference ignoring signs). Also computed for the two major phases (and for the full cycle) is the average change in the index relatives per month, obtained by dividing the amplitudes by the duration of the phase in months.

S(3) the secular movements as given by the average monthly standings in absolute units during expansion, contraction, and the full cycle, together with percentage changes from phase to phase.

³ Series definitely established as inverted are treated on a peak to peak basis. Also many non-inverted series are treated on the peak to peak basis to offer more complete comparison.

⁴ Sometimes less, depending on the duration of the complete cycle.

S(4) the specific cycle pattern, which is indicative of amplitude and which is an expansion of table S(2), showing the cyclical relatives of the full cycle in 9 distinct stages. Stages I, V and IX represent the beginning trough, the intermediate peak, and the terminal trough, respectively; stages II, III, and IV represent the index relatives for each third of the intervening expansion phase; and stages VI, VII, VIII represent the index relatives for each third of the intervening contraction phase.

S(5) the specific cycle pattern expressed as the average change per month between the 9 stages indicated in table S-4.

The second set of methods leads to the construction of three R (reference cycle) tables, representing the same individual series, but the relatives are now classified in accordance with the previously established turning points of the general business cycle.

These enumerate:

R(1) the reference cycle pattern indicative of amplitudes in the 9 stage set-up of table S-4. This permits direct comparison of the specific cycle pattern of table S-4 with the reference cycle pattern of table R-1.

R(2) the reference cycle pattern expressed as the average change per month between the 9 stages indicated in table R-1. It is interesting to note that the average monthly change during reference contractions may frequently be positive because of a continuing positive slope after the reference peak, although such positive increments here become smaller.

R(3) a general index of specific cycle conformity with reference cycles. The signs of amplitude differences during reference cycle expansions, contractions and the full cycle are examined. A similar investigation of signs is applied to the average change per month analysis.

As a summarizing measure, each of the S and R tables contains column averages representing the duration, timing, amplitude, and pattern of the cycles of individual series. Average deviations, between cycles, are presented for these factors. From the summaries of table S-4 and R-1, basic graphs are prepared for ease in interpretation (see chart 21). These graphs, which first struck the present reviewers as too complicated for ready comprehension, are really masterpieces of inclusiveness. From them the reader is able to obtain information regarding the average duration and its variability, the average amplitude and its variability, the average timing and a direct comparison between the slopes of the average specific and the average reference cycles.

In the examination of the many series included in the study, it was concluded that reference cycles of the same series bear a family resemblance to the average pattern (see charts 73 and 74). Likewise, the patterns of reference cycles for separate series were seen to differ characteristically. Averages of cyclical timing, amplitudes, and the average change per month, when subjected to tests of significance, were found to be significantly different among series. However, the authors observe "... that although cyclical measures of individual series usually vary greatly from one cycle to the next, there is a pronounced tendency toward repetition in the relations among the movements

of different activities in successive business cycles" (pp. 488, 491). It was also found that the variance ratios of full cycle durations were not large enough to be considered significant.

Arguments leading to the choice of the various statistical tools and methods (monthly data in preference to annual or quarterly data, seasonal adjustments, inter-cycle trend removal rather than a combined inter-intra-cycle trend removal, three-month averages at turning points rather than formal smoothing) are clearly enumerated in Chapters 6 through 8. The customary method of trend fitting and removal is abandoned because it tends to alter dates of the turning points, because it introduces greater uniformity in cyclical gyrations than is warranted, and because trend fitting is at best a rough approximation of true growth. It was observed that the elimination of random fluctuations by the application of "smoothing" formulas tends to change the dates of turning points (sometimes by as much as 6 to 10 months), tends to stretch out the durations and to dampen the amplitudes of brief cyclical phases, assumes an unwarranted inflexibility in the shape of cyclical rhythms since the formulas used are quite rigid, and does not eliminate random movements that extend over years.

In establishing the validity of averages as a basis of comparison, the authors were compelled to investigate the hypothetical influences of secular, discontinuous, and long-wave movements on general business cycles. For if these influences were predominant, the perusal of the average pattern of specific and reference cycles would yield trivial results. Using either the coefficient of determination (coefficient of correlation squared) or simple variance analysis by establishing significant groups, and sometimes both, the authors offer proof, though they grant it not conclusive,⁵ that the above mentioned factors do not alter the course of business cycles with any degree of significance.

Following is a highly condensed outline of some of the hypotheses tested and the implications deduced:

1. a. Hypothesis—that secular change tends to expand cyclical durations and amplitudes whereas secular decline tends to dampen them.

b. Deduction—with the exception of the amplitudes of call money rates, the influence of secular tendencies cannot here be considered significant.

2. a. Hypothesis⁶—that as industrial development progresses and a stage of "economic stability" is reached, business cycle durations tend to increase.

b. Deduction—although the hypothesis may be substantiated by us-

⁵ The authors point out the roughness of the use of simple variance analysis as a test of significance. Such a test assumes independence of the component elements which in fact is not true for cyclical components. Also, the series are in many cases too short in duration to permit any definite conclusion.

⁶ By F. C. Mills, "An Hypothesis Concerning the Duration of Business Cycles," *Journal of the American Statistical Association*, December, 1926.

ing dates of turning points derived from Thorp's *Business Annals*, the addition of more recent fluctuations and the use of turning point dates derived from the present study fail to support the hypothesis.

3. a. Hypothesis—that the business cycles after 1914 indicate a definite structural change.

b. Deduction—that although there is an apparent tendency toward intensified cyclical fluctuations after that date, the apparition is not clear.

4. a. Hypothesis—that long waves of from 50 to 60 years in wholesale prices⁷ influence the duration and amplitude of specific cycles.

b. Deduction—that although there is better evidence that an association exists between price trends and specific cycles in terms of cyclical duration⁸ than in terms of cyclical amplitude, the sample series indicate that the relations among the cyclical patterns are broadly similar during the periods of expansion and contraction in wholesale prices. Also, the authors find it difficult to state with any degree of certainty that wholesale prices have distinct long-period turning points, offering as evidence the several portions of the curves which are actually quite flat for extended periods of time.

5. a. Hypothesis—that within major cyclical movements of from 9 to 10 years (Juglar cycles) there appear three minor cycles with an approximate duration of 40 months (Kitchin cycles).⁹

b. Deduction—that no arrangement of the Burns-Mitchell specific cycles in groups of three consecutive cycles produces an approximation to the Juglar cycles of 9 or 10 years duration.

An interesting general finding concerning the nature and dating of cyclical ~~downward~~ is presented, not in the chapters on hypotheses, but in an earlier passage: “. . . when the turns in leading activities are comparatively ‘flat,’ crisscrossed by erratic movements and dispersed over many months, the turn in general business activity becomes elusive. The American business-cycle peak of 1937 approximates this type. . . . It may be noted parenthetically that this evidence [wide dispersion in the peaks of numerous series], so far as it goes, gives no support to J. M. Keynes’ thesis that “*the substitution of a downward for an upward tendency often takes place suddenly and violently, whereas there is, as a rule no such sharp turning-point when an upward is substituted for a downward tendency.*”¹⁰ Here is ample evidence, if it be needed, that many of Keynes’ original and undeniably brilliant contributions to economics require not blind acceptance as part of a system but critical empirical examination, verification, refutation, and re-synthesis.

Enough has been said to suggest the elaborate and careful nature of this

⁷ Long waves as originally derived by N. D. Kondratieff.

⁸ This was especially true during the contraction phase where variance analysis ratios proved significantly large.

⁹ Hypothesis as formulated by J. A. Schumpeter in his three schema postulate.

¹⁰ Page 83 and 83 n. The Keynes quotation is from his *General Theory*, p. 314. Italics supplied.

major contribution to the literature of cycle measurement and appraisal.¹¹ *Measuring Business Cycles* represents not only a synopsis of new statistical techniques applied to a very large number of cyclical questions, but also portrays in great detail the problems involved in applying many older techniques to individual series. As a systematic statistical analysis that may eventually lead to generalized explanations, the approach taken by Burns and Mitchell is by far the most significant effort made to date. Although the undertaking is tremendous in its scope, the development of the detailed picture of what happens during "typical" business cycles may prove tremendously fruitful.

No one can read this book without admiration for the care and scientific zeal of the authors. It exemplifies Wesley Mitchell's predominant intellectual passion throughout his whole life: the constant testing and searching to verify or to refute hypotheses and theories. It is good to know that the enormous loss to economics occasioned by Dr. Mitchell's death is at least mitigated in the field of cyclical research by the fact that the basic analytical techniques, established in this volume, will be further applied by Dr. Burns and the staff of the National Bureau in their continued efforts to produce "a systematic account of how business cycles run their course."

ROBERT F. BERNER
RALPH C. EPSTEIN

The University of Buffalo

¹¹ Minor criticism might suggest that the use of the phrase "rate of change," to designate an average absolute monthly spread between relatives, may not be the happiest use of terms; for such a measure represents an average monthly difference between two indexes but not the percentage rate by which anything grows or diminishes. But in other sciences, "rates" sometimes are expressed in absolute rather than proportionate terms (e.g., velocity as, say, miles per unit of time) so the authors may be justified, and the reviewers merely picayune, on this point.

The Keys to Prosperity. By WILLFORD I. KING. (New York: Constitution and Free Enterprise Foundation. 1948. Pp. xvii, 242. \$4.00.)

Intended as a restatement of "the basic essentials underlying national prosperity," this volume provides a sad commentary on what the proponents of the extreme right are willing to accept as "sound economics." Some of Dr. King's seventeen "keys to prosperity" would be accepted by nearly everyone wishing to retain a largely free-enterprise economy, although the full statement in certain cases reveals more than first meets the eye.¹ A few of the "keys," however, will make even ardent conservatives gasp. One is "Forcing of the thriftless to insure themselves and their families against the untoward vicissitudes of life," which is elaborated in the body of the book to mean no form of government-supported social security whatsoever and the substitution therefor of compulsory disability insurance, to be provided by private companies and paid for entirely by payroll deductions (p. 87). Dr. King believes that, "in large part," cases of individual need are due to "thriftlessness" (p. 86). Another key is "Avoidance of governmental deficits, in bad years as well as in good years." Another is "Withdrawal of government from the

¹ The seventeen keys are listed on page 233 of the book.

ownership, administration, or control of the operations of construction projects, farms, factories, banks, insurance funds, and transportation facilities." And, of course, there is the proposal that "the thrifty" be protected "from confiscation of their savings by taxation and otherwise." The reader is not told precisely what degree of progressiveness in tax rates represents "confiscation."

There are sections of this book which are reasonably satisfactory as an elementary exposition. But the scientific merit of the book as a whole is not unfairly illustrated by such passages as the following:

After 1929 in the United States, "Social security and unemployment insurance payments were used as bribes to keep people from working" (p. 23).

"Monopolies not sponsored by government, but yet able through monopolistic power to raise prices sufficiently to oppress the public, are and have been extremely rare and short-lived. . . . The more one looks into the matter, the more convincing becomes the evidence that in the United States, at least, all oppressive monopolies are protégés of government" (p. 27).

Since real "saving" was less in the 'thirties than the 'twenties, "the belief that 'over-saving' is a characteristic of depression would seem to lack any foundation in fact" (p. 45).

"The fact which [the Keynesians] overlook is that public spending to relieve distress nearly always perpetuates and accentuates that distress. In countries not rich enough to afford any considerable volume of charity, depressions are short-lived, for hunger soon compels able-bodied persons to accept jobs at the best wages obtainable. When the idle go back to work, production increases, and the depression inevitably fades away. In prosperous nations, by contrast, doles may keep millions idle for years, and their idleness brings about general depression, lessens the national output, and keeps the nation poor" (p. 81).

"When spending equals income, there obviously is no hoarding" (p. 131). But spending is defined to include not merely consumption but also "amounts spent for savings bonds, for life insurance, for savings-bank deposits, for building and loan shares, and for numerous other classes of investments" (p. 130).

"The facts thus far set forth make it abundantly clear that the prosperity of a nation is commonly bound up with that ultra-important ratio

$$\frac{\text{Net new spending power}}{\text{Average hourly earnings}} \text{ (p. 193).}$$

["Net new spending power" is defined as national income plus change in the sum of currency and total demand deposits.]

As a corollary, "Depressions are, therefore, brought about by the inflexibility of wage rates—by their failure to drop when the net total of new spending power declines" (p. 191).

"What labor monopolies, collective bargaining, strikes, minimum wage laws, and unemployment insurance have really accomplished is to cut down production, throw millions out of work, reduce total payrolls billions of dollars in a single year, discourage thrift, and promote inflation, lawlessness, and riots" (p. 213).

Passages such as these make it difficult to take seriously any of King's

proposals, which, on the side of maintaining economic stability, boil down to combining price stabilization through monetary control with wage rates made as flexible as dividends.

One final point will explain why I have chosen to devote this much space to a book of such dubious merit. *The Keys to Prosperity* is published by "The Constitution and Free Enterprise Foundation" and distributed by its parent, the Committee for Constitutional Government. There is apparently under way a program aimed at the colleges "to promote the free enterprise system and the best available book on economics, *The Keys to Prosperity*."² I must also report—with mingled sadness and mystification—that a brochure advertising this book (a "classic for today's students of economics as, for its time, was *The Wealth of Nations*") quotes a dozen laudatory opinions by "economists and other experts," at least six of whom are university economists with some national reputation.

Business Finance; Investments and Security Markets; Insurance

Corporation Finance. By HIRAM L. JOME. (New York: Henry Holt. 1948. Pp. x, 676. \$4.00.)

Professor Jome has written a text for students whose only previous preparation has been a beginning course in economics. He has assumed, further, that most students using this book will not pursue further professional studies in the field. The book's scope, therefore, is considerably wider than that of most textbooks on corporation finance.

Part I on the Forms of Business Organization begins with a brief exposition of elementary accounting principles. These are based on the financial transactions of Bill Anthony, a "boy in your neighborhood," who subsequently goes into business with partners and eventually incorporates. This treatment lessens the danger that students will fail to see the connection of what they study with the everyday life they know.

The second part of the book is devoted to Corporate Problems. It includes chapters on corporate securities, capital structure, internal and external sources of financing and combinations. The treatment is not always reasonably balanced. The subject of working capital is discussed in about three pages, whereas three long chapters are devoted to combinations. For a non-professional student who is more likely to be concerned with small rather than large enterprise, working capital financing is surely a more important subject than corporate combinations.

Discussion of the legal phases of corporate finance, for the layman, should emphasize the need for conforming to the statutes and judicial precedents. Yet, discussing the legality of dividend payments, Professor Jome says that

paid-in surplus "should probably not be used as a basis for cash dividends," whereas the layman must be warned, first and foremost, that this is illegal in a number of states.

Part III of Professor Jome's book is headed Social Aspects of Corporation Finance, but actually includes a large amount of material ordinarily found in books on investment. There are chapters on the mathematics of investment, securities exchanges, the security laws, protective provisions in stock and bond contracts and investment trusts. Where the student is going to take a separate course in investments, as is often the case, a number of these chapters may be found inappropriate for the course in corporation finance.

There are well-chosen brief appendices that provide valuable readings for students.

The author has produced a readable, interesting text. Useful problems are placed at the end of the chapters. For nonprofessional students, especially those who are not going to take a separate course in investments and for whom considerable outside reading is not practicable, this book will be found among the most suitable available.

New York University

Public Finance

Introduction to Fiscal Policy. By RICHARD W. LINDHOLM. (New York: Pittman. 1948. Pp. 248. \$2.75.)

This book is intended to fill a pressing need felt by instructors in public finance for a more adequate treatment of modern views on fiscal policy than is obtainable in most textbooks. In the few instances where major emphasis has been placed on the relation of fiscal policy to income, employment, consumption, and the price level, there has been a tendency to slight important matters covered in textbooks patterned along more conventional lines. Yet, if both tasks are to be accomplished in the same volume, public finance texts might become extremely cumbersome. One possible solution of this problem is an auxiliary text like the present, of modest length, and not too expensive, for purchase along with the major text.

In his preface the author states that the book is to be read by the "average student of political science, education, sociology and history, as well as business and economics." Yet everything of importance for fiscal policy is "concisely and thoroughly treated." It may be asked at once whether either of these objectives has been, or indeed can be, achieved. Fiscal policy cannot really be understood without a grounding in monetary theory, and an understanding of business cycle theory must underlie any but a docile acceptance of fiscal policy dogma. It is also a question how far a treatment of fiscal policy running to 225 pages can be at the same time both thorough and concise. Thoroughness has indeed been achieved with respect to the range of topics considered, but at the cost, in some instances, of rather brief treatment. The book commences with an introductory discussion devoted to the

relation between the public and private economies, the development of the fiscal role of the government from World War I to the present time, and definitions of the terms commonly used in the field of fiscal policy. There follows a chapter on what modern fiscal policy includes, which forms the pattern for the remainder of the book. The *laissez-faire* and the interventionist attitudes toward public finance are contrasted, and types and goals of fiscal activity are discussed. Fiscal activity can affect not only the general level of prices, but relative prices as well, and thus the way in which resources are used. But it is also important to maintain the correct volume of consumption, to preserve the proper balance between savings and investment, and to avoid unemployment; and this in turn requires fiscal intervention to assure an economic distribution of income. These desiderata are then discussed in the main body of the volume, in relation to (1) revenues and (2) expenditures.

In the two major chapters, on revenues and expenditures, there are parallel sections on each of the following: desirable prices, a desirable consumption level, a desirable employment level and a desirable income distribution. Desirable prices are stable prices. The desirable consumption level is that which at the same time maximizes labor effectiveness and provides savings adequate to assure the introduction of efficient machines, as well as a demand adequate to assure that these savings will be invested. The desirable employment level is full employment. The desirable income distribution is that which minimizes the reduction of efficiency through inadequate income (p. 63). For the most part these desiderata are assumed, which is appropriate for those acquainted with the logic by which they are reached, but which is apt to leave that student at a loss who is untutored in such matters as the relative desirability of rising, constant, or falling prices; the role of the propensity to consume; the equality of savings and investment; the inflationary implications of full employment; and the economic effects of unequal distribution of income.

The chapter on the revenue system is introduced by a brief discussion of built-in revenue flexibility. While it is pointed out that this automatic corrective "can aid greatly" in bringing about stable prices, consumption, and employment and a desirable distribution of income, somewhat more space might have been devoted to disposing of the more exaggerated claims that have been implicitly made by those who rely on stable tax rates to smooth out moderate fluctuations in income. Some attention is given to shifting and incidence of taxation, whence the analysis proceeds to the relation of revenues to desirable prices. The difficulties of steering a course between inflation and deflation are pointed out, and the "adjustable tax plan" for achieving stable prices is discussed. This leads to a treatment of war and postwar inflation problems and how they were met, followed by a catalog of the ways in which revenue-raising activity affects consumption (taxes, commodity sales, government borrowing, effects *via* the interest rate and gold sales). The possibilities of achieving full employment by way of the tax system with a balanced budget are explored, followed by a discussion of the effects of taxes on investment and consumption, and the taxation of idle money. Appropriately, the author devotes a relatively large amount of space to the role of the

tax system (including state and local) in the redistribution of income. The author's argument (p. 129) that the carrying charges of the debt "are certain to bring about a greater concentration of income in the upper brackets" should be noted by those advocates of fiscal intervention who have minimized the importance of the economic effects of the public debt.

A discussion of the effects of expenditures on prices during different phases of the cycle is followed by details concerning the wartime experience, government operation of yardstick plants, purchase of gold, interest expenditure, and debt repayment. The use of government expenditures to achieve a desirable consumption level naturally receives a relatively large amount of space, but the framework of the book works against a really adequate treatment of the relation between fiscal policy and willingness to invest. Some interesting remarks are made with respect to pump-priming, however, the position being taken that this device is useless unless first "needed changes in the relationship of different economic factors have been made" (p. 170). The chapter concludes with a treatment of the possibilities of effecting redistribution of income through government spending; vertical redistribution of income, social security, education, interest payments, and agricultural expenditures.

A final chapter deals with problems of administration. The Employment Act of 1946 is summarized and discussed, followed by a treatment of the problems of debt management, government debt and inflation, and the effects of interest rate policy. The problems related to successful administration of taxes and expenditures are next handled, including those of creating an adequate reserve shelf of public works, contract-letting, timing and the like.

This book is a sincere effort to bring the problem of fiscal policy down to the level of the elementary student. If care is taken to supplement its materials with classroom discussion of the relevant underlying monetary and business cycle theory, it should fill a needed gap. The question may be raised, however, whether even in an "Introduction" it would not have been advantageous to include some discussion of the latter along with the treatment of fiscal policy proper.

KENYON E. POOLE

Northwestern University

The Monetary Problem of France. By PIERRE DIETERLEN and CHARLES RIST.

Published for the Carnegie Endowment for International Peace. (New York: King's Crown Press. 1948. Pp. xiii, 98. \$2.50.)

This book by Mr. Pierre Dieterlen of the French National Economic Intelligence Center, in collaboration with Professor Charles Rist, is the second study of European monetary policies published by the Carnegie Endowment for International Peace. However, unlike Professor Leon H. Dupriez' account of the *Monetary Reconstruction in Belgium*, which dealt with the scope, technique, and results of the Belgian monetary reform,¹ the Dieterlen-Rist book is limited to describing France's problems of internal inflation and ex-

¹ For a review of Professor Dupriez' book by the present reviewer, see the *American Economic Review*, March, 1948, pp. 177-80.

ternal unbalance and then strongly advocating a solution along "classical" lines. The authors of the book, as Mr. Antonin Basch remarks in his foreword, urge such a solution "in plain and courageous language," not hesitating "to underscore the mistakes which were made and to emphasize what, according to their opinion, must be done to restore order and prosperity to the French economy."

Professor Rist, who wrote the preface and one chapter outlining the reversal in France's financial and economic policy in January, 1948, holds that France committed grave mistakes in the early postwar years. Military expenditures were increased after the liberation to a level that in no way corresponded to France's actual needs and was quite out of proportion to its resources; the government tolerated for several years a large budgetary deficit; and it embarked upon an extensive modernization and re-equipment program which was "on much too broad a scale considering the financial limitations of an impoverished country." These mistakes were further aggravated by the "obsession" with the theories of controlled economy and by the consequent attempts to achieve economic recovery "in an atmosphere of financial and monetary insecurity." To effect a "rational monetary policy oriented towards the return to a much greater freedom," Professor Rist recommends re-establishing domestic stability by balancing the government budget, renewing confidence in the nation's currency, and giving impetus to saving. Furthermore, since "reality is not concealed by throwing a smoke screen around it," domestic stability, according to Professor Rist, should be consolidated by creating open gold and exchange markets where the franc would be given a realistic value, thus restraining imports, stimulating exports, inducing the repatriation of French capital abroad, attracting private foreign investments to France, and last but not least, providing the necessary precondition to dishoarding private gold stocks (put at 3,000 metric tons or 3.4 billion dollars). With the help of the European Recovery Program, which enables France to import certain essential products without straining its foreign exchange market, Frenchmen could then face "fearlessly" the new freedom.

Some, though by no means all, of the ideas put forward by Professor Rist became official policy in January, 1948; yet, a new outburst of inflation occurred in the second half of 1948. In undertaking to explain why inflation is chronic in France, Mr. Dieterlen's masterly analysis, which constitutes the bulk of the book, so guides us through the labyrinth of France's currency and public finance that even the events subsequent to the completion of the manuscript (early 1948) appear in sharper perspective. That Mr. Dieterlen's survey does not appear outdated is due to the fact that the author traces the postwar developments back to the 'thirties while simultaneously concentrating upon the broad lines of the narrative rather than embroidering it with incidental details. As a result, the mosaic of French contemporary currency and public finance that he sets forth appears highly instructive and very interesting.

Mr. Dieterlen's analysis brings home to the reader the complexity of France's monetary problem. First of all, as the author rightly points out, French monetary and fiscal policy is "incomprehensible" without bearing in

mind French politics—the “liberation psychosis,” the swing to the left in the political assemblies, the disrespect of law (“a penchant quite in conformity with French temperament”), etc. The “anarchic attitude” that is a sequel of wartime demoralization was further aggravated by the inability of the French government to organize effective rationing that would assure the vital minimum to all its citizens. Under this “endemic disorder” any attempt at disinflating was exceedingly difficult.

Furthermore, the French government coalitions between the Socialist and Center parties brought about constant vacillation between economic controls and a liberal economic policy. Inconsistent compromises had to be made between those who favored controls and those who rejected them in principle while tolerating them for reasons of expediency. Yet, in Mr. Dieterlen’s words, the “French economy remains a capitalist economy; to maintain a certain number of excessive compulsions, and particularly monetary compulsions, is inefficient as well as detrimental to its mechanism. It is therefore necessary either to radically transform the economic system of the country (with all the political consequences that such a transformation implies) or to readjust the monetary policy to the pattern of the existing economy.”

Finally, although Mr. Dieterlen agrees with the French planners that the solution of France’s monetary problem “requires 130 per cent of the 1938 production” (actually industrial production is above prewar while agriculture is still below prewar), he strongly objects to any inference that “apart from external loans negotiated between governments and from the combined modernization of basic industries, there is no salvation for French economy and its currency.” Indeed, the author sees “other possibilities,” along the lines of Poincaré’s stabilization of 1926-28.

As Mr. Basch reminds us in his foreword, Professor Rist had “his share in Poincaré’s program, and the dominant impression we get in reading the book is that the authors are firmly convinced that France today can benefit from its own experience of twenty years ago. Is there, however, any such analogy between the problem that France faced in 1926 and that which confronts it today? As an answer to this fundamental question, let me point out that, at the start of Poincaré’s stabilization, the level of production was higher in France than in 1947-48; the government budget was broadly balanced; and stabilization could be accomplished through a simple change in the psychological climate: to renew confidence it was sufficient to persuade the French to refrain from demanding repayment of national defense bills and from sending abroad the francs thus obtained. Although the difficulties which France faced in 1926 should not by any means be underestimated, its present economic ills are much deeper today. France consumes more than it produces and is living on its capital and on other nations’ aid; its public finance position, in spite of the genuine improvement this year, remains uncertain; and quite apart from balancing the government budget through additional taxation, it must save enough to finance the large-scale investments it embarked upon to make good the war damage and the neglect of the interwar years. Under these circumstances, monetary stabilization is a more complex undertaking than twenty years ago. Yet, Dieterlen and Rist rightly

insist that without monetary stabilization no real economic and social progress can be achieved, and that by putting in order its money and public finance, France can enhance its stature in the Atlantic community.

M. A. KRIZ

New York, N.Y.

Monetary Reconstruction in Italy. By BRUNO FOA. Published for The Carnegie Endowment for International Peace. (New York: King's Crown Press. 1949. Pp. x, 147. \$2.25.)

Unlike its predecessors which were by European authors, this third book in the Carnegie Endowment series on European monetary policies was written by an American citizen, a consulting economist by profession and advisor of the Italian Economic Delegation in Washington. Yet, in reading this excellently written book, one is struck by the warmth of its author's feeling for his native Italy.

While full of comprehension for Italy's "truly formidable difficulties," the author is on balance critical of Italy's economic and monetary policies during the period from 1945 until early 1947 when the wait-and-see policy was finally abandoned. He, however, greatly admires the policy since 1947—the "financial masterpiece" of Luigi Einaudi, a professor of economics who, after an enforced semi-retirement under the fascist regime, reached high office in his seventies, serving successively as governor of the Bank of Italy, Deputy Prime Minister and Minister for the Budget, and President of the Italian Republic. The bulk of the book depicts the Italian inflation in terms of this fundamental approach, while the two concluding chapters deal with monetary and economic reconstruction, both through Italy's own effort and through the Marshall Plan.

Italy's inflation, by-product of the fascist economic and military adventure, was accentuated by the post-liberation drift "along the lines of least resistance." In the first place, according to Foa, the Allies were at fault because they neglected what might have been done to mitigate the impact of their expenditures in Italy (Foa holds that the military lira rate was inflationary—an allegation denied by Southard in "The Finances of European Liberation"). Secondly, the Italian policy-makers and administrators, veering toward *laissez faire* and deferring to the "views and whims of minor American officials," "welcomed the practical difficulties" that stood in the way of economic controls, thus buying economic freedom at the cost of additional inflationary pressure. Thirdly, as a result of an "unstable but working compromise" under which the conservative parties agreed to sliding wage scales and the freezing of employment in industry while the leftist parties refrained from pressing for extensive social reforms, wages caught up with or by the end of 1947 even outstripped the increase in the official cost of living—the comparative social peace of this period being secured at the price of a further impetus to inflation. Fourthly, the continuous government deficit financing, while to some extent merely reflecting the inordinate price rise, is blamed for the large additional inflation of 1946-1947. Finally, the premature, partial restoration of the free foreign exchange market in March, 1946 injected into the Italian economy "the

vagaries inherent in exchange depreciation." The new exchange regime was "unsettling," as well as "ultimately incompatible" with the maintenance of domestic price stability.

Among his criticisms, the author puts considerable emphasis on the absence of a "major operation on the currency," which would have entailed a temporary blocking of currency and a capital levy on liquid assets. Had such an operation been supported by conservative economic and financial circles, it would have had "a very good chance of success." Actually, the advocacy of stringent monetary and tax measures was left to the radical parties, while the opinion of those who supported such measures on purely technical and economic grounds carried little weight "in an atmosphere dominated by old-fashioned economic theories." Indeed, the Italian economists and the government were "excessively influenced" by concern lest a currency freeze be detrimental to "confidence" and the propensity to save. In any event, having discarded the idea of a currency reform, the government adopted a "spurious compromise" by simultaneously floating a long-term loan exempt from any future capital levy and declaring its intent to introduce such a levy in the near future. The loan was actually issued and a capital levy adopted, against the background of a rapidly deteriorating situation.

Finally the Bank of Italy, far from being "a purely passive vehicle of government policy," took the initiative in April and again in August, 1947 to arrest the inflation by "a vigorous and ruthless dose of credit control." As was repeatedly emphasized by Mr. Einaudi in defending himself against "savage criticisms," this was not a deflation but "a natural and necessary corrective"—a surgery, not therapy. The effects of the new policy on the exchange rates and prices were "sensational"; under the impact of large-scale dehoarding these dropped sharply, thus paving the way toward a new stabilization. In November, 1947, the lira became officially a floating currency—"an extremely bold and novel experiment," which turned out to be very successful.

The author is fully aware that his strong criticisms of the pre-Einaudi era may appear inconsistent with his post-Einaudi praise. To take an example, why should the floating lira of 1946 be bad while that of 1947 was excellent? In the author's opinion, the justification of 1947 rests partly on the differences in the underlying conditions, but essentially on "the vigorous prior intervention in the field of credit which had shaped the underlying economic conditions to such an extent as to make it possible to move toward a free exchange market."

Against the bright side of the Einaudi policy, the author sets its shadows—a 20 to 25 per cent decline in industrial production towards the close of 1947, as compared with the early months of that year. Yet the credit restriction, although quantitative rather than selective, "was not too severe." Indeed, it was necessary in order to "dam the tide of inflation" in a situation that was highly explosive. Another drawback was the growing recourse by industry to government credit, either directly or through the I.R.I., the powerfully government-controlled industrial holding company. The unexpected by-product of the Einaudi policy was thus a shift of the financing burden from the banks

to the government and the growing control of the government over large segments of industry. Last but not least, Italy's industrial economy was so weakened by credit restrictions that there resulted a "ludicrous" situation in which it was unable to absorb fully the fuels and raw material made available under the ERP. Under these circumstances, the author suggests stepping up the rate of Italy's industrial output to the level required to effectively absorb ERP aid. "Grave doubts," however, remain as to Italy's ability to reap the full benefits of ERP.

"Dominated by a combination of obsolete ideas and brilliant improvisations," Italy's economic policy arrested the inflation in 1947, while in 1948 it made remarkable progress toward closing the gap in the balance of payments. There is, however, another side to the picture. The balance-of-payments deficit has been cut merely because Italy's industrial output and national income, and therefore her imports of industrial raw materials and foodstuffs, have been lower than they would have been under conditions of fuller employment. In other words, Italy has solved its balance-of-payments problem largely at the cost of chronic unemployment, the present level of unemployment being almost twice the prewar. With a "bolder, more dynamic, and more aggressive" policy, such as Mr. Foa advocates in his conclusion, Italy might attempt to increase the rate of investment and the standards of consumption; but at what level, and in what way, would it then be possible to close the balance of payments? This is the fundamental dilemma that not only Italy but other ERP countries, together with the ECA, face today.

M. A. KRIZ

New York, N.Y.

Public Finance. By WILLIAM WITHERS. (New York: American Book Company. 1948. Pp. ix, 489. \$4.25.)

At the beginning of his preface the author states that he has prepared this general text "only because of the urgent need for a *Public Finance* conceived along new lines." The average American reader will infer that he means along Keynesian or New Deal lines, though by implication he criticizes existing texts, not only for their failure to integrate public finance with the main body of economics, but also because of: (1) their over-emphasis of factual detail and inadequate treatment of fiscal problems, (2) meager consideration of the American background of economic and political trends, (3) failure to maintain a socio-economic point of view, (4) failure to recognize the conflicts in economic and political philosophy which underlie all public finance thinking and discussion, (5) failure to view "public finance as a crucial aspect of the growth of the public economy and to appreciate its relationship with the private economy, and (6) lack of "a simple style which the student can follow without undue effort." He goes on to say:

If there is one major purpose of this book, it is to present the problems and conflicting issues which have arisen from the increasing encroachment of public finance on private enterprise. The theory and content of public finance are changing rapidly with the changing relationships between business and government. The author is aware that the New Deal is but one aspect of

a world-wide trend toward greater public economy. He believes that the teacher has an obligation to create an awareness of this trend in the minds of his students and to give them some appreciation of the seriousness of its implications.

The text, which is not more than half or two-thirds as long as most similar treatises in this field, is divided into six parts: introduction, public revenues, public expenditures, fiscal coordination, public debt, and the economics (incidence and effects) of public finance.

Aside from its emphasis upon Keynesian doctrines, one of the most unusual features of this volume is its Introduction. This takes up one-fourth of the entire text and is composed mostly of what might be called a tax or financial history of the United States. Thus the author supplies the background which his preface implies others have unfortunately overlooked. He sketches 150 years of the perennial conflicts of the large commercial, financial and other business interests on the one side, with the farmer, labor and small merchant interests on the other side—the struggles of the Jeffersonians against the Hamiltonians. Ardent New Dealers will be much more pleased with this sketch and interpretation than will their partisan opponents. The latter will probably dub the Introduction and, in fact, the whole book “propaganda,” whereas the author considers it much needed educational instruction or illumination.

Except for the Keynesian slant (not all of which is as new or radical as some seem to think), the treatment of the important taxes and classes of revenue commonly employed in the United States is not greatly different from that of most texts. Because of the long introduction and the smallness of the volume, less than the usual amount of space is given to the discussion of various taxes, expenditures and other phases of public finance.

The author accepts, and presents more clearly than many, most of the Keynesian theories of over-saving, under-investment, “pump priming,” compensatory taxing, spending, borrowing and debt management. He approves particularly the use of fiscal policy to control business cycles and to provide full employment of labor and resources, but repeatedly emphasizes “that public expenditures constitute a more effective business control device than taxes.”

He is usually careful to present traditional views as well as newer theories so that the student can compare their merits and weaknesses. This, together with his numerous introductory and summary outlines—often in question form—make his text unusually provocative and teachable. There are so many controversial matters, however, and so much is necessarily omitted from such a small text that the instructor should be unusually well prepared and not have too large a class for two-way discussion.

The author apparently has no doubt that there will be a growing acceptance of Keynesian doctrines and a more than proportional, as well as an absolute, growth of the public economy as compared with the private economy; in fact, that this is necessary for the survival of private enterprise—if its survival is possible.

It does not seem appropriate to itemize minor errors and inaccuracies which

are not more than usual for a first edition. Though this volume does not contain anything that cannot be found elsewhere, it is, nevertheless, a good brief presentation that should be made, and as such it is a welcome addition to the growing supply of texts in this field.

Apparently the author, after more mature thought, decided he may have overstated his case and that he should hedge it with a caution. At any rate, the reviewer was interested to find at the end of the volume the following which is a very good summary of what he had decided to say by way of comment:

We must exercise caution in using public finance to control business fluctuations. Economists are by no means in agreement as to the causes of business cycles. Until these causes can accurately be isolated and measured, fiscal policies for control cannot be planned with assurance. The cure of the business cycle "disease" is now in an experimental stage. Economic "doctors" prescribe remedies based on hypotheses rather than on sound scientific knowledge. Furthermore, the fiscal system is only one among many influences on the economic system, and its effects in bringing recovery must not be over-emphasized. To be sure, public finance exercises a broader and more powerful influence as the public economy grows. This growth may now have proceeded to the point where the public economy is the central balancing influence even in the United States, but other factors must not be forgotten, such as interest rates, the size of inventories, market speculation, and the rate of private investment.

While the reviewer is inclined to agree that, under certain conditions, there is probably much validity to many of the proposals of the author (who is much less extreme than some), he nevertheless considers that several of the fundamental assumptions have not been proved and does not agree that the "burden of disproving" these assumptions and conclusions based upon them "rests with private enterprise" any more than the burden of proving them rests with the proponents of the suggested changes.

ROY G. BLAKEY

University of California at Los Angeles

British Block Grants and Central Local Finance. By R. E. CARLSON. Johns Hopkins Univ. Studies in Historical and Political Science, Ser. LXV, No. 1. (Baltimore: Johns Hopkins Univ. Press. 1947. Pp. 222.)

It must always be very difficult for an outsider to grasp the significance and nuances of such intimate features of another country as are implied in its central/local fiscal relations, at least without extensive personal contacts. Professor Carlson has been singularly unlucky in the timing of his study of the British system of exchequer grants to local authorities. The war prevented him not merely from making such contacts, but also from obtaining access to a number of research studies relevant to his subject. It also greatly delayed not merely the completion of the work, which bears somewhat obvious signs of having been written at different periods, but also, it would appear, its publication. In spite of the use in the last chapter of an article on Derating which was published early in 1945, the analysis of the book essentially ends

with 1944. Since that date there has been a complete revolution not only in the grant system, but also in many of the powers and duties of local authorities which affect their financial position.

While these difficulties and deficiencies must seriously detract from the general usefulness of the book, Professor Carlson has brought together a great deal of information dealing with the grant system since 1888 which will doubtless be serviceable to American students who have not convenient access to further reading. The earlier chapters deal with the period up to the Local Government Act of 1929; the treatment is purely descriptive, and Professor Carlson relies heavily on secondary sources such as Dr. Newcomer's *Central and Local Finance* and my own *Finance of British Government*.

There follows a chapter on local government finance in World War II which is perhaps the best in the book—Professor Carlson has worked carefully through the documents—but apart from exhibiting in exaggerated form the traditional process of pull baker pull devil between the Treasury and the local authorities, by which changes in British local finance normally come about, the episode is now of historical interest only. The one substantial change of function, the nationalisation of fire brigades, has already been reversed—somewhat to the chagrin of the local authorities who now find themselves saddled with a vastly expanded service, quite unnecessarily elaborate for normal conditions.

Of scarcely more than historical interest also are the postwar plans which Professor Carlson examines at length in the following chapter. So far, things have not turned out much like that—except for the emphasis on equalising rateable value per head, on the one hand, and crude population figures on the other, as exclusive measures of the appropriateness of areas for local government purposes (a policy which can be directly traced to the Labour Party and National Association of Local Government Officers plans), and which is now being embodied, on the one hand, in the grant provisions of the Local Government Act of 1948, and on the other, in the efforts of the Local Boundary Commission to amalgamate counties which have substandard populations, much against the desires of the inhabitants, and regardless of physical features and natural lines of communication.

While not wishing to cavil over details, it is perhaps desirable to draw attention to certain points in which Professor Carlson's statements tend to give a misleading emphasis. In the first place, the importance of differences in valuation practice is exaggerated (and hence the usefulness of Rateable Value per head as a measure of relative wealth is underestimated). This is not Professor Carlson's fault: he was unaware of the very important information on rents and rates collected by the Ministry of Health and analysed by my husband and myself.¹ These figures are relevant to the problem of grants in at least three respects: (1) There is virtually no evidence of deliberate undervaluation in order to improve eligibility for grants; (2) on the contrary, a persistent tendency was observed for the poorer areas to be more highly valued than the more wealthy—an additional reason why the grant system

¹ *The Problem of Valuation for Rating*, Cambridge Univ. Press, 1943.

has been less equalising than was hoped; and (3) as a partial explanation of (2) there has been in the interwar period a persistent undervaluation of small new (post-1918) houses in relation to others. Thus, prior to the derating of industry, houses were, by current valuation practice, already enjoying a substantial degree of "derating," a circumstance which partly explains the agitation for industrial derating, as constituting in a sense a compensation for industry.

Again, it is not (as stated on p. 71) the assessment of rates on occupiers which gives rise to interlocal shifting of population; this is an inescapable phenomenon of any local tax where liability varies substantially from area to area. Nor was there "widespread default" by ratepayers during the depression; on the contrary, default was much lower than for the property tax in the United States. Indeed, the evidence suggests that a tax assessed on occupation can be more easily collected in depression than a tax on ownership; especially when liability represents only a modest proportion of even the unskilled labourer's budget—as is the case with rates,² thanks to the presence of the grant system.

Finally, on the problem of size in local government areas, it is very easy to exaggerate the wastes due to uneconomically small areas in the British local government system. In one sense, the problem has never been solved merely because the optimum size has continually expanded with improvements in transport and in administrative technique; in another sense, with the concentration of services under the county councils and county boroughs—a process which has been proceeding for a generation—it has lost, in the view of many, the greater part of its significance. The County Councils now administer directly the services for which a large area is appropriate.

The greatest weakness from which Professor Carlson's book suffers—and this again is not Professor Carlson's fault—is the omission of the revolutionary changes in local/central financial relations which have taken place since 1944. Here it is not possible to do more than list some of the most important of these. In the first place, the transfer of virtually all their trading services to national bodies has lost local authorities some revenue; but much more important, it has taken away a great slice of their more interesting powers and duties, thus seriously reducing popular interest in local government. The power of the central government has also been increased by denying local authorities direct access to the capital market, under an arrangement that looks like being permanent. Thirdly, the new health service, operating from the summer of 1948, has transferred local authority hospitals to *ad hoc* regional authorities (combining local authority and voluntary hospitals) thus removing an important source of disequalising expenditure. At the same time, it is already evident that both the health service and the educational changes are going to be much more costly than was originally envisaged; so that eventually the pressure on local treasuries will be heavy.

Transcending all other changes in importance, however, are the provisions

² Cf. J. R. and U. K. Hicks: *The Incidence of Local Rates in Great Britain*, Cambridge Univ. Press, 1944.

of the Local Government Act of 1948, and more particularly the new grant regulations, which substitute an "equalisation grant"³ based, almost solely, on rateable value per head and current expenditure, for the block grant, and available only to those areas whose rateable value per head (as adjusted by the provisions of the act) is less than the national average. In this new system traditional Treasury caution has been thrown to the winds, not merely in acceding to an annual revision of grants, but also in agreeing to underwrite additional local expenditure in a manner which, viewed in the light of the past, is frankly staggering. It is already apparent that the invitation to additional spending by the poorer areas is not falling on deaf ears.

International Economics

Foreign Economic Policy for the United States. Edited by SEYMOUR E. HARRIS. (Cambridge: Harvard Univ. Press. 1948. Pp. xiii, 490. \$6.00.)

An excellent group of essays by twenty-four economists and civil servants has been brought together in this volume by that most indefatigable of editors, Seymour E. Harris. The book does not attempt to cover all aspects of American foreign economic policy; there is no mention, for instance, of shipping, aviation, or telecommunications, no discussion of the work of the Economic and Social Council of United Nations, the International Labor Organization, or the Food and Agriculture Organization, and no systematic consideration of problems relating to strategic resources, economic development, or international investment. But the central issues of policy are presented with clarity and subjected to penetrating analysis.

The book is divided into five parts. In the first, Thomas C. Blaisdell, Jr., and Eugene M. Braderman describe the organization through which the government of the United States formulates and administers its foreign economic policies. In the second, eight authors outline the problems presented to American policy-makers by the economic difficulties of other countries; John M. Cassels and Randall Hinshaw write on Great Britain, J. K. Galbraith on Germany, Robert W. Barnett on Japan, Robert B. Bryce on Canada, Henry C. Wallich on Latin America, Paul A. Baran on the Soviet Union, and John D. Sumner on China. The essays in Part III deal with international agreements and agencies: Allen G. B. Fisher and Camille Gutt explain the policies of the Bank and the Fund, Winthrop G. Brown describes the General Agreement on Tariffs and Trade, and Harry C. Hawkins discusses the problems that arose in negotiating the Charter of the International Trade Organization. Part IV is devoted to the European recovery program: Edward S. Mason is concerned with its significance in terms of political strategy, Sidney S. Alexander with the extent of Europe's needs, Calvin B. Hoover with the prospects for self-help and mutual aid, Kirtley F. Mather

with the relation of the program to American resources, and Lincoln Gordon with the operating problems of the Economic Cooperation Administration. In the final section of the book, the theoretical issues raised by the concept of fundamental disequilibrium are discussed by Alvin H. Hansen, Gottfried Haberler, Paul A. Samuelson, Robert Triffin, and Thomas Balogh.

No reader of these essays can fail to be impressed with the increasing scope and complexity of the international economic interests of the United States, the predominance of our influence, and the extent of our responsibilities. We must learn how to deal with the complete collectivism of the East and the partial collectivism of the West. We must put our defeated enemies back on their feet and, until we do so, we must continue to feed them. We must finance the reconstruction of Europe, insure the recovery of production, and promote the expansion of trade. We must contribute to the economic development of the backward areas of the world. We must take the lead in organizing and strengthening the agencies of international cooperation. And we must act, in all of these matters, with such wisdom, skill, and circumspection that other nations cannot take offense. This is the prescription; it will not be an easy one to fill.

The central theme of the book is the shortage of dollars. It appears in the discussion of the British balance-of-payments deficit, in the description of the economic prostration of Germany and Japan, in the study of trade between the East and the West, in the examination of the problems of Latin America, and in the analysis of the difficulties of Canada. It explains the qualifications that have been written into the postwar agreements on currency and trade and the disappointing performance, up to now, of the Bank and the Fund. It justifies the European recovery program. Most of the authors touch upon this subject, in one way or another, and many of them discuss its causes and explore the possibilities of a cure.

Among the causes, emphasis is placed by some of the contributors upon such structural maladjustments as disorganization of production, international indebtedness, loss of foreign assets, markets, and earning power, and relative changes in productivity, and by others upon mistaken national policies: heavy public expenditures, monetary mismanagement, and the inability or unwillingness of governments to permit necessary adjustments. The prospects for the restoration of equilibrium are viewed with varying degrees of skepticism. Balogh and Haberler represent the two extremes. According to the former, balance between the United States and the rest of the world is unobtainable: the superior technical efficiency of American industry will enable it to undersell its competitors all along the line. According to the latter, balance can theoretically be achieved through adjustment to new conditions of comparative cost; but it is recognized that adjustment may be obstructed by politics. As Samuelson remarks, moreover, disequilibrium may persist as long as the United States is willing to lend and lose and lend again. There is no disposition, however, to force a restoration of balance by prompt alteration of rates of exchange; a free market, at the present time, would not evoke an adequate flow of trade; it would reduce Germany, Austria, Greece, and Italy to starvation and chaos; it would impose upon Western Europe and the

United Kingdom a standard of living that might prove to be politically untenable. But most of the authors would agree that a solution must eventually be sought in devaluation of currencies, suppression of inflation, and enhancement of productivity abroad and in maintenance of employment and increasing absorption of imports by the United States.

Mr. Harris is apparently a strong believer in freedom of speech. At any rate, he has permitted his book to close with a slashing attack on American policy that is frequently inaccurate, generally ill-tempered, and completely inconsistent with everything that has gone before. Mr. Balogh, in the concluding essay, denounces the Bretton Woods Agreements, the ITO Charter, and the General Agreement on Tariffs and Trade, and presents a special plea for the adoption, by the United Kingdom, of a permanent policy of deliberate and systematic discrimination.

Most of England's troubles, it appears to Mr. Balogh, have their origin on this side of the Atlantic. We are too big and strong; anything we do is sure to be wrong. We are determined to have a depression: our imports will fall and England will suffer. Inexplicably, we may prosper: our competitive ability will increase and England will suffer. Our motives are unworthy: we espouse policies that "will tend to perpetuate the present superiority of the United States in relation to other industrial exporters" (p. 474). We won't commit ourselves to cut our tariffs when we fall into depression (p. 473). "The fact that neither the General Agreement nor the Charter outlaws tied loans—a most powerful and discriminating means to promote exports—shows that the United States, well aware of its war promoted superiority, means to retain it" (p. 478). We persistently discriminate against efforts to establish a large-scale economic territory in Europe (p. 477). Small wonder that "the poorer countries begin to suspect that—under the guise of attractive slogans—their relative and absolute inferiority is to be stabilized and their social stability is to be sacrificed . . ." (p. 476).

Much of this is deliberately misleading and much of it is simply untrue. The United Kingdom did not seek to include in the Havana Charter any provision requiring the United States to reduce its tariffs unilaterally in the event of a depression or any provision whatsoever relating to tied loans. It may have escaped Mr. Balogh's attention that the American tariff has been reduced, through trade agreement negotiations and price changes, from a weighted average ad valorem equivalent of 48 per cent in 1930 to one of 15 per cent in 1948. He should, however, be aware that a small minority of American loans is tied, that the 3¾ billion dollar loan to the United Kingdom was not, and that the many billions extended in grants and loans under the Marshall Plan are not. The tied loans are open to criticism, but to complain of them and to ignore the much larger volume of untied loans and grants, of which England has been the principal beneficiary, is to be less than honest in argument. It should be noted, finally, that the allegation of American opposition to the creation of a large-scale economic territory in Europe will come as something of a surprise to the administrators and the foreign representatives of the ECA.

There is one American policy of which Mr. Balogh apparently approves.

He likes the generosity of ERP and looks for more generous treatment by the United States in years to come. But he hopes "that the price paid in renewed political conflict will not be too high and that undue fiscal restrictions on the American administrators of the program will not result in humiliating and harmful dictates of policy leading to strife in Europe and worsened relations with America" (p. 480). A fitting comment appears at the close of the essay by Mr. Mason: "Let us not expect too much from this program in the way of popular approbation abroad. Even if all the European requirements stated in the Paris report were supplied without question by the United States, I doubt whether we should be regarded as a generous big brother. The figure of Lady Bountiful is not an endearing one in literature. And when the position of Lady Bountiful is taken by a country which has half the world's industrial output and enjoys a standard of living unmatched elsewhere, it is too much to expect that she shall be voted the most popular member of the class. The one most likely to succeed, perhaps, but not the most popular" (pp. 296-97).

CLAIR WILCOX

Swarthmore College

Major Problems of United States Foreign Policy, 1948-49—A Study Guide.
(Washington: The Brookings Institution. Pp. ix, 246. Paper, \$1.50; cloth, \$3.00.)

In 1946 there was established, as an integral part of the well-known Brookings Institution, an "International Studies Group." This group, composed of some eight or nine members of the Brookings staff, is engaged under the able and experienced direction of Mr. Leo Pasvolksy with the important undertaking of producing an annual document dealing with United States foreign policy. The declared purpose of the document is, first, "to aid in the development of an informed and responsible American public opinion on Foreign Policy" and second, "to contribute toward a more realistic training of the increasing number of American specialists in International Relations." In keeping with this dual purpose the document is aimed primarily at students in colleges and universities, discussion group leaders, public lecturers, editorial writers, commentators, and professional men generally.

The document under review is the second of the annual volumes. Compared with its predecessor, it exhibits a marked improvement in format, style and organization, adds a considerable body of new material and reflects an understandable shift in content and emphasis. At the same time, it retains the identic assumption regarding foreign policy and the same approach to its understanding that were emphatically visible and widely applauded in the initial volume. Although neither the assumption nor approach are altogether new, their explicit formulation is sufficiently unorthodox to give significance to the entire venture. The document is not just another book on foreign policy.

The assumption is the relatively simple one that an understanding of

foreign policy is enhanced by looking at it through the lenses of responsible government officials charged with the duty of making decisions. The approach is called the "problem" method.

Assumption and approach combine to inject into the study of international relations a spirit of sharp realism, admirably calculated to serve as a counter balance to the approach of many extremists who, either unaware of the restraints imposed on policy making or restless in the face of them, advocate "ideal" solutions to concrete problems. Followers of Mr. Wallace and advocates of World Government will not find in this document anything which necessarily refutes their views on foreign policy. What they will find is a different approach, a different "time" orientation and a sharpened area of concentration. The document speaks not to the dilemmas of a distant future, but to the problems of a distraught present.

Among the problems of the present, the Japanese Peace Settlement, Economic Assistance to Latin America and the Veto Problem in the United Nations were considered sufficiently pressing to justify special treatment in what are called "Problem Papers." (The conspicuous absence of Germany is explained by its presence in the preceding volume and by subsequent coverage in monthly supplements which keep the basic documents up to date.) The "Problem Papers" occupy approximately half the volume, the other half being devoted to background material describing "The Present Position of the United States in World Affairs" (approximately 30 pages), a "Review of Major Problems," analyzed both geographically and functionally (approximately 100 pages), and helpful appendices including a description of the complicated mechanism for the conduct of United States foreign relations.

The "problem" approach reaches beyond description, in that specific "issues" are ferreted out, identified and then broken down into alternative courses of action, only one of which, presumably, may be chosen by the harassed policy maker. This approach, which bears some resemblance to the intellectual processes embedded in the well-known military "estimate of the situation," presumably reflects actual practice and in so doing brings instruction in foreign policy down to earth. By way of example, the "Problem of Economic Assistance to Latin America" is broken down into six major issues, each calling for policy decisions to which are added four other issues on which an expression of United States policy would be desirable, even though decisions may be postponed. A typical issue of the former kind concerns steps to be taken to stimulate private investment, one alternative being "to pursue a hands-off policy until the Latin American Governments themselves create a favorable climate for foreign investment," the other being to attempt to negotiate agreements along the lines set forth at Bogota. In the body of the document reasons for choosing each alternative are concisely indicated without, however, any expression of preference.

Perhaps enough has been said to show the nature of the volume under review and the character of the enterprise of which it is an important part.

Great care has been manifested in its preparation including, during the drafting stage, the solicited criticism of many individuals concerned directly or indirectly with foreign policy. Its virtues, and they are virtues of a high order, are that it has tended to supply a spirit of realistic inquiry in a field not altogether noted for rigorous analysis. Furthermore, it may be expected that the work will continue to improve as experience demonstrates the need, which this reviewer, at least, believes to exist, for reaching beyond the present effort to one which not only identifies and fragmentizes issues, but relates them back to a set of carefully analyzed "interests" ("objectives"?) so that value judgments may be made with a clearer understanding of their implications for the national security, world stability, the economic well-being of the people or the desire to encourage democratic tendencies the world over. If it is possible to speak of a weak spot in the present volume, it is believed it can be found in that part of the document. (pp. 9-27) in which this is attempted. Lack of rigour is evident, not alone in the verbal confusion caused by the too indiscriminate use of such terms as "aims," "objectives," "responsibilities," "interests," "ideals," "principles," "attitudes" and "forces," but in the failure to show clearly the character and extent of our interests, their relation to general policies and the relation between general policies and specific commitments. It is worth remarking that in the absence of some such frame of reference, value judgments are apt to be obscured and hunch, common sense, or assumed wisdom tend to steal the show.

The document under review, despite the great care which has gone into its preparation, provides this frame of reference only partially by a brief preliminary sketch dealing with the "bases" of United States foreign policy followed by a careful but purely descriptive account of recent developments. This is believed to be insufficient even after allowance is made for the fact that the document attempts to avoid value judgments by refraining from advocating any particular policy or set of policies. Alternatives are stated but not "evaluated." Given the purposes of the publication, this sense of restraint is commendable. It may be indulged, however, while still recognizing that value judgments are implicit in the sifting of "relevant" facts, the identification of issues and the statement of alternatives as Messrs. Gromyko, Vyshinsky and Molotov would readily discover should they chance to study them. What is urged is not that value judgments be made explicit but that the basis for making them be analyzed more thoroughly. Or, to repeat, that a better framework be supplied against which to project the analysis of facts, issues, and alternatives.

It may be objected that this would require another book and thus falls outside the scope of legitimate criticism. By way of answer it is suggested that this is the heart of the business and thus deserves more respectable treatment by a group which in the short space of three years has already demonstrated its high capacity by making a worth-while and distinctive contribution toward creating a more informed opinion on foreign affairs, and a better understanding of the practical dilemmas confronting policy makers.

HARDY C. DILLARD

University of Virginia

Great Britain in the World Economy. By ALFRED EDWARD KAHN. (New York: Columbia University Press, 1946. Pp. xvii, 308. \$4.00.)

The value of this study lies partly in the clear and precise account which it gives of the long-run trends which weakened and undermined the British world economic position during the years 1919-1939 and the economic and policy adjustments of that period. It lies partly in the theoretical framework within which these events are discussed.

Mr. Kahn is in search of an "organic theory of international equilibrium" which will prove more helpful and enlightening for the study of the basic changes in the world economy now taking place than the "accepted" theory. The only fruitful analysis of the balance of payments "must," he feels, "be in terms of actual cyclical and secular process, of actual complex patterns of cause and effect in mutual interplay and in continual transition, constantly disrupting and readjusting to a real world." He criticizes "accepted" theory mainly because of its tendency to isolate a single cause of maladjustment and then rest content with showing that equilibrating forces will be set in motion. This neglects the nature of the transition during which the equilibrating forces are operative, the cyclical and secular factors that may make the adjustment difficult or easy, and many other relevant considerations.

For these reasons, Mr. Kahn presents his material as, in part, "a case study" for the development of an organic theory. In developing this approach he defines "equilibrium" in a country's balance of payments as "a situation in which over a period of time long enough to exclude seasonal and minor discrepancies the total supply and demand for means of foreign payment are equated, without continuous short-term capital or gold movements in one direction, or sizable fluctuations in the external value of currencies, or default, or measures of control employed to maintain this equality."

Mr. Kahn does not, as sometimes happens, neglect his theoretical approach when dealing with his historical material. He consistently uses the British experience to illustrate the simultaneous operation of the various complex elements leading away from and towards equilibrium that are to be part of the completed organic theory. His emphasis throughout is on the basic long-run trends that have been responsible for weakening the British international economic position and on the economic and policy adaptations to this changed position. He fully recognizes, of course, that the changes in public policy of 1931-32 were a revolutionary readaptation to a changing world situation after the failure of an attempt to rebuild along traditional lines. But he consistently treats the real determinants of British economic policy as independent economic forces, largely beyond the power of British policy to control, and operating continuously over the whole period.

These real determinants are discussed in a general chapter on The Deteriorating Position of British Industry and two chapters on The Decline and Adjustments of the Staple Trades and The Expanding Industries. These chapters are very well balanced. They contain a good deal of cogent criticism of industrial organization and management in Great Britain, particularly of the so-called industrial self-government of the period, but they end on a hopeful note. Mr. Kahn concludes that there was, during these years, a sub-

stantial adjustment to an altered international competitive position in the staple trades, and a successful adaptation of the economy as a whole to the altered international position of British industry.

With this preparation Mr. Kahn analyzes the basic trends in the British balance of payments from 1919-1939 and the adjustments of policy before and after the abandonment of the gold standard. It is in these chapters that the character of the book as a case study towards an organic theory of international equilibrium is most strongly brought out. This gives to a survey of very familiar material an interest and freshness of treatment that will be appreciated by those who have long labored in the field.

The basic problem posed by Mr. Kahn's book is whether or not, in the interwar period, the adjustments in the British economy to an altered international position laid a solid foundation for working out the long-run problems that have persisted into the post-World War II period. In this connection his discussion of the shifting geographical pattern of British exports and imports over the long period 1815-1939 has a special value. In this long perspective he finds that the withdrawal of Britain into a "more closed and regulated regional system, with Britain as the center, attempting to maintain ever closer economic ties with younger, largely primary producing countries of the empire and sterling area" was but an intensification of trends apparent well before 1929 and even 1914. Mr. Kahn, however, reaches a rather firm conclusion that the opportunistic and defensive policies which characterized British foreign trade policy at the end of the inter-war period were being pursued at too great a sacrifice of the advantages of genuine multilateralism. Had not the Second World War intervened, the time would have been ripe for a reversal of policy.

In concluding chapters on The Position of Britain in the Post War World, written during the war itself, and before the Marshall Plan, Mr. Kahn ventures some speculative answers to his basic questions. Since these look beyond the readjustments of the immediate postwar period they have not become out of date. What Mr. Kahn foresees is a period of even greater strain on the British balance of payments than in 1919-39, partly due to the stimulation of competing industrial production rather than primary production by international investment. This can, however, be substantially offset, by a far more effective reconstruction, reorganization and re-equipment of Britain's productive machine for the satisfaction of the demands of the home market than was carried through from 1919-1939. Much will depend on whether or not the sum total of world trade will be increasing so that a diminished share in this trade by the United Kingdom will not entail an absolute decline in British foreign trade.

Mr. Kahn's book contains many interesting discussions of special points such as the long-range shifts in Britain's terms of trade, the changing relations between her capital export and her trade balance, and the changing pattern of triangular settlement between the United Kingdom, the rest of the sterling area, and the rest of the world.

WILLIAM ADAMS BROWN, JR.

Brookings Institution

Le Plan Marshall. By FRANÇOIS PERROUX. (Paris: Librairie de Médecis. 1948. Pp. 222. 200 fr.)

Grandeur ou Décadence du Plan Marshall. By J. LÉVY-JACQUEMIN. (Paris: Librairie Marcel Rivière et Cie. 1948. Pp. 75. 120 fr.)

These two French books on the Marshall Plan may be considered remarkable not so much for their content as for what they do not say. In neither of them is any word of the concrete recovery problems facing France or Europe. Of the three aspects of the Marshall Plan—self-help, mutual help and aid from the United States—these books deal only with the last.

If they deal with the Marshall Plan mainly from the familiar point of view of United States aid, however, neither book is without interest for the American economist. Perroux' most interesting essay deals with the responsibilities of an "internationally dominant economy," *i.e.*, the United States. Lévy-Jacquemin offers a new theory of international economics and a concrete proposal to replace the antiquated "equilibrium system." Neither book may be said to deal definitively with the Marshall Plan or disequilibrium in international trade and finance; both are readable and suggestive.

Perroux' five essays, first published over the thirteen months from June 1947 to June 1948, appear to have been designed to reassure worried French readers. The first article, apparently written before both the Harvard speech and the Molotov response to it, defends economic cooperation among neighbors, whatever the attitude of the big powers. The last three set forth an analytical description of the Marshall Plan and its evolution from 19th century private lending via the "neo-liberalism" of the Bretton Woods agreements.

It is in his second essay on the internationally dominant economy, however, that Perroux is at his most paradoxical and suggestive. The Marxist view of economic imperialism, he indicates, is naïve. The theory of imperfect competition has been inadequately applied to international relations, but it is clear that a dominant economy may have a more effective course of action, in the long-run, than short-run exploitation. The intentions of the United States, by inference, may be held to be honorable because the United States, like any other oligopolist, finds it pays in the long run to behave honorably. International economics based upon trade among equal partners is irrelevant to today's problems.

Lévy-Jacquemin is also disposed to jettison a great deal of the classical apparatus, including primarily the major premise of a continuous tendency to equilibrium. In his view, the system operates to perpetuate disequilibrium. Countries should be ranked in a system A, B, C, and D, each tending to have an export surplus *vis-à-vis* countries in the next lower category. At the present time, the United States finds itself in category A; Canada, Argentina, Brazil, etc., in B; Britain, France, Italy in C; and at the end of the scale in D, the backward and underdeveloped countries of the world. The tendency of the United States to perpetual surplus arises from the American propensity to oversave or underconsume combined with our political unwillingness to spend on internal public works.

The measure needed to make this system function, in Lévy-Jacquemin's view, is loans by the United States to backward areas made through the countries of Europe. Offshore purchases under the Marshall Plan are a step in the right direction and a major advance from the tied loans of the Export-Import Bank and Bretton Woods, which are incompatible with multilateralism. After the fruition of the current European investment, however, the next requirement is continuous loans from A to D, so contrived as to let B and C balance their accounts multilaterally.

This thesis cannot of course be taken at its face value. It is asserted rather than argued. And far more important, it neglects the propensity of the United States to import on balance from raw material and tropical areas. Yet it contains flashes of insight, which have a bearing on the rationale behind Point 4 of President Truman's inaugural speech.

In short, both books are worth a perusal.

C. P. KINDLEBERGER

Business Administration

Marketing: Principles and Methods. By CHARLES F. PHILLIPS and DELBERT J. DUNCAN. (Chicago: Richard D. Irwin. 1948. Pp. x, 729. \$6.00.)

Introduction to Marketing. By PAUL D. CONVERSE and FRED M. JONES. (New York: Prentice-Hall. 1948. Pp. viii, 606. \$5.65.)

The basic pattern of textbooks in marketing was established some years ago and has seldom been violated. New books, and revisions of old ones, have been justified chiefly by substitution of current statistics and citations for obsolete ones, but the concepts and topics have remained unchanged. The books under review exhibit minor variations from the pattern, but are unlikely to provide any surprises for marketing instructors. On the other hand, judging from the unsophisticated discovery of marketing facts recently evidenced by anti-marginalist writers in economic journals, those economists who have never read any marketing book might do very well to examine one or both of these.

The Converse and Jones volume is an offshoot from a well-established marketing textbook by Converse. It is deliberately designed as a more popular presentation, and seems aimed at high school students or nonacademic small businessmen. Perhaps the market for such a work commercially justifies its publication. It hardly seems suitable, however, for a course in marketing at the collegiate level. The chief innovation of the book is its emphasis on retailing; 368 of its 588 text pages are devoted to this topic. The approach of this section is on "how to run a store." This undoubtedly has an appeal for thousands of readers, since there are more small businessmen in retailing than in any other economic category. For such readers, this book may be considered better than the usual popular work on retailing, since it does provide some background of general marketing. Moreover, students find retailing easier and more familiar than any other phase of marketing, and the opera-

tional approach appeals to many of them as "practical." The condensation of other standard marketing material, however, means that a student using this text only would be inadequately informed on marketing in general. Nor would he find in this volume any guide to further reading, for there are no bibliographies and the footnote citations are notably sparse.

The Phillips and Duncan volume covers the usual material of marketing in a thoroughly satisfying way. The statistics and references are copious and up-to-the-minute, and the statistics are better organized and digested than is common in marketing books. In its effect on most marketing writers, the inauguration of the Census of Distribution in 1930 was the worst thing that could have happened to development of the study of marketing, for it has resulted in textbooks filled with figures on the number of middlemen of each type, their sales volume, etc. Phillips and Duncan have done better by these data, in pointing up the significance of various Census tabulations. They have, beyond that, been conscientious in seeking for non-census sources to bring their figures up to date in so far as possible. Further evidence of careful preparation is shown by the excellent reading references and the listing, for each chapter, of Harvard cases appropriate for use with the text material.

A differentiating feature of the book is its emphasis on the consumer. Two of the early chapters are devoted to the ultimate consumer's buying motives and problems and most of one chapter to consumer statistics; this is followed, contrary to custom, by a chapter on the industrial user. The preface explains that it is recognized that the customer—whether household consumer or industrial user—is the proper starting point for all marketing plans. But the text material goes beyond the viewpoint of the sales manager and the strategy of exploitation of the consumer. In one chapter, the marketing system is examined from the viewpoint of the consumer, and is found somewhat wanting; there follows a discussion of the "consumer movement" and the business and government aids to the consumer. The authors' interest in the consumer is shown further by a lengthier section on consumer co-operatives than is usual.

While Phillips and Duncan do not go very far in satisfying the current demand for development of marketing theory, their chapters on pricing remain the strongest to be found in marketing texts. The theory of monopolistic competition, which Phillips introduced to marketing texts in his 1938 edition, is briefly but adequately explained. It is followed, however, by the customary series of unrelated and unanalyzed paragraphs on various pricing policies used by manufacturers and merchants. These marketing facts regarding pricing practices stand as a challenge to economists and marketing students alike; perhaps theory in both fields may be improved by more serious consideration of the relation of marketing price policies to economic theory.

E. R. HAWKINS

Johns Hopkins University

Introduction to Business. By LEWIS A. FROMAN. (Chicago: Richard D. Irwin. 1948. Pp. xxv, 601. \$4.25.)

This book is written as a text to be used in a first course in business.

Its usefulness, as is the case with textbooks generally, will depend on such factors as the relation of the course to other courses in the curriculum, the equipment of the students and the reliance placed by the instructor on the textbook.

In many institutions the typical student in a first course in business is a college freshman without business experience who is taking courses in the social sciences simultaneously and who will ultimately have the benefit of a comprehensive curriculum. At the other extreme is the beginning student in the evening division who is likely to be more mature and experienced but who will not be taking any other "general" course at the same time and who may benefit from an introduction to the social sciences as well as an introduction to business.

Dr. Froman's book appears to be planned with the interests of the latter group of students in view. In a section on "The Functions of Business Enterprise" there is a page on the hedonistic concept of choice and a paragraph which distinguishes capitalism, socialism, and communism. Treatments of roundabout production, risk bearing and Utopian socialism are included.

The other sections of the book include one on "The Nature of Business Enterprise" containing chapters on Manufacturing, Extractive, Public Utilities and Trade and Service Industries as well as Financial Enterprises and Agriculture. The section on "Problems of the Business Unit" has chapters on Form, Size, Internal Organization, Management Controls and Employee Relations. The final section is concerned with "The Role of Government" and includes chapters on Monopoly Regulation, Taxation and Government Enterprises.

These matters are presented so that the student always remains at a safe distance from the turmoil, triumphs and anxieties of business operations and the problems confronting society receive greater emphasis than those which consume most of the time of business management. For instance, the discussion of public utilities includes paragraphs on natural monopoly, the importance of coal as a source of energy and defines watergas and coke-oven gas. It gives little idea of the nature of the problems to which the management of a public utility devotes itself and the characteristics which would distinguish a well-run utility from one poorly run.

The chapter on financial enterprises devotes a paragraph to the fact that national banks issued bank notes before 1935 and a page and a half to credit unions. It gives no idea of commercial banking as a business in which some prosper and others fail or the relationship of the business enterprise to its banker. Bonds are treated only from the point of view of the investor and not from the point of view of the borrower.

There are some who believe that a major function of the introductory course in business is to provide an insight into business as a career. Not only the college freshman, but a large proportion of the students in clerical or other routine jobs who attend evening courses have very little idea what an executive of a copper company, a tire manufacturer or a brokerage house really does. Every course might well strive to indicate the problems, the

skills, and the challenges which specific careers in business afford. No textbook can do this job by itself but every introductory text might well assume its share of this responsibility. Dr. Froman is likely to find that his colleagues in the social sciences will supply any deficiencies he might leave if he sacrificed breadth for penetration and inspiration. He cannot assume that similar help is available to supply the demands of the young man or woman seeking guidance toward a career.

Industrial Organization and Markets; Public Regulation of Business

Small Business: Its Place and Problems. A Research Study of the Committee for Economic Development. By A. D. H. KAPLAN. (New York: McGraw-Hill. 1948. Pp. xiv, 281. \$3.25.)

Within the last decade and a half the subject of small business has gradually emerged as a new and recognizable segment of economic inquiry, with its own fields of research and its own niche in the structure of economic theory. This new study, prepared by Dr. Kaplan for the Committee on Economic Development, represents the most comprehensive and inclusive contribution yet made to the small but rapidly growing body of economic literature in the field. Taken in conjunction with Steindl's work on the place of small business in economic theory¹ and Weissman's work on the financial problems of small firms,² Dr. Kaplan's well-organized and clearly presented study should provide the reader with an adequate knowledge of most of the theoretical and practical problems in the field, the principal topics of research, the major points of controversy, and the bases for the development of a sound public policy.

Quite properly, Dr. Kaplan begins his work with an analysis of the various standards used in defining small business. He arrives at a composite definition in which the principal elements are "1 million for volume of business, \$500,000 for total assets, and 250 employees for personnel," with the type of firm consisting of a "single independent organization directly under the supervision of its owners who are also its managers—whether incorporated or not." Although to some this definition may seem to take in a lot of territory, it falls far short of Thurmond Arnold's highly pertinent definition of small business as any firm which is unable to maintain a lobbyist in Washington.

Dr. Kaplan then summarizes available statistical evidence on the position of small business in the various branches of the economy, on trends in the business population, on discontinuances and failures, on longevity and turnover, and related topics in the general field of business structure.

Moving from structural to functional characteristics, he next examines the highly important subject of the relationship of size to efficiency. Although here again he offers no new primary data, the conclusions which he derives

¹ Joseph Steindl, *Small and Big Business* (Oxford, Basil Blackwell, 1945).

² R. L. Weissman, *Small Business and Venture Capital* (New York, Harper, 1945).

from the existent information on unit costs and profits represent an excellent summary of the state of present knowledge. Thus his principal conclusions are: "(1) The differences in efficiency among the small enterprises themselves are more extreme than those between small and large firms. . . . (2) The middle size firms of an industry commonly make a better average showing on costs and earnings than do either the giants or the smallest members. (3) The over-all tendency is for unit costs to diminish as size increases until the big-business category is reached. But the very largest member of an industry does not usually show the lowest cost or the best profit rate on invested capital. In most cases a firm in the middle range makes the best showing, and frequently a small firm leads the industry in this respect."

The remainder of the book is devoted to the three types of corrective action most urgently needed by small business—management assistance, financial aid, and the preservation of competition. In regard to the first, Dr. Kaplan emphasizes the pervasive absence of management guidance for small business, which all too often is compounded by the reluctance of the small enterpriser to learn new methods and techniques. In addition to a needed expansion in private sources of management assistance, as in trade associations, industrial engineering, market-research firms, etc., Dr. Kaplan feels that "the Bureau of Standards should be authorized to serve small-business groups more aggressively with respect to information on technological developments," and that the Department of Commerce should act as a "clearing-house," gathering and disseminating technical information through the various organizations and agencies serving small business.

In regard to financial aid, Dr. Kaplan summarizes the various studies which have been made on this problem and comes to the inevitable conclusions that, by and large, small firms are unable to secure funds through the security markets; that even when the small company is able to use this avenue, the costs of flotation are all but prohibitive; that long-term credit, though on the increase, is still far from being generally available to small business; and that direct investment by individuals has tended to dry up, due largely to the high rates of taxation and to the progressive concentration of population in large cities, with the consequent weakening of personal ties and relationships. After surveying the various proposals which have been advanced to meet this problem, including community industrial development organizations, direct government loans, and loan insurance (the last being treated in a rather cursory and uncritical manner),³ Dr. Kaplan recommends the establishment of a network of capital banks under Federal Reserve Board supervision, with the commercial banks in each Federal Reserve district authorized to subscribe a small percentage of their capital and surplus in a district

³ Pp. 167-68. For a fuller presentation of a possible loan insurance program, see House Small Business Committee, 79th Cong., 1st sess., *Hearings*, Pt. 2, H.R. 64, *Financial Problems of Small Business*, 1945, pp. 997-1031; Smaller War Plants Corp., *18th Bimonthly Report to Congress, June 1945*, pp. 11-14; and House Agriculture Committee, Special Subcommittee on Cotton, 80th Cong., 1st sess. (Pace Committee), *Hearings*, 1947, pp. 586-87.

capital bank, which initially could grant credit and perhaps eventually purchase the stock of small firms. As a means of greatly expanding its ability to render financial aid, Dr. Kaplan suggests that each capital bank might be "put in a position to place its debentures or rediscount paper with the Federal Reserve Banks at rates low enough to permit a fair return on the expanded employment of its funds."

In his final chapter, "Competition—Means and Ends," Dr. Kaplan describes the effects on small wholesalers and small manufacturers of the forward expansion by large producers into the distribution field; cites the "introductory pricing" and other recently revealed discriminatory practices of the A. & P. as illustrative of those types of activities against which no small distributor can possibly compete; condemns the fair-trade laws and argues that small business in supporting them is actually working against its own best interests; denounces interstate trade barriers and similar legal restrictions to a free market; advocates a reform of the patent laws; and urges labor organizations to be flexible in dealing with small business and not to expect small competitive firms to be able to meet the same terms and conditions as can be granted by large firms enjoying a monopolistic position.

In the opinion of this reviewer, this well-rounded work has only one flaw, which however is a serious one, namely the comparative lack of attention given to the problem of economic concentration, a problem which certainly deserves somewhat more consideration in a discussion of the "place and problems" of small business. This criticism is based on the following observations:

1. In analyzing the position of small business, he relies principally on data relating to the *number of small firms*, rather than the *proportion* of activity or resources accounted for by small business. This use of data on numbers, which incidentally leads to some optimistic inferences concerning the position of small business that would not be supported by data on proportions, is particularly surprising in view of (a) Dr. Kaplan's own recognition of the great weakness of data on numbers, which are tremendously influenced by the turnover in one-man and other tiny establishments (*cf.* pp. 43, 56, 234), and (b) the existence and availability of a large body of statistical information on proportions which could have been used in the analysis.

2. In the one-and-a-third pages which he does devote to the topic, "Industrial Concentration," he fails to cite any of the available data on the level or trend of concentration, as measured on a corporate or company basis, confining his analysis to the "establishment" or plant data of the Census of Manufactures (pp. 38-39). Although most of the material that he does cite, which incidentally is limited to the period 1929-39, indicates a general increase in concentration, about half of this brief discussion is concerned with something which Dr. Kaplan describes as a "hopeful aspect," namely, a slight decline which took place in the relative share accounted for by the largest size group. This decrease, however, was probably due in large part to the decline in general economic activity, or more specifically to

the greater-than-average decreases which probably took place in the most highly concentrated fields—heavy goods, capital equipment, etc.

3. Dr. Kaplan makes a number of assertions which seem to imply that the proper place of small business should, or, at least, will be as an adjunct or “auxiliary,” rather than as a competitor, to big business. Thus, “It is more likely that small enterprise will develop as auxiliary to its larger competitors” (p. 52; *cf.* also, pp. 103, 235). In view of the conclusions which he has arrived at concerning the relationship of size to efficiency, such an observation necessarily implies that the dominance of big business and the “auxiliary” status of small business will be the result of non-efficiency factors, *e.g.*, greater economic power, resources, etc. Not only has Dr. Kaplan failed to spell out this logical conclusion of his argument, but he has also failed to exhibit any particular concern over such a state of affairs.

4. Although he recognizes the existence of the postwar merger movement, he quickly dismisses it as a factor of any importance, stating that the “phenomenon has not, however, reached the proportions of the decade following the First World War” (p. 234). This, of course, is a perfectly safe observation since it would be rather difficult for the merger movement to have achieved the same “proportions” in the three years following World War II that it attained in the “decade” following World War I. If Dr. Kaplan had compared the current merger movement to the first three years rather than to the “decade” following World War I, his statement would still have been true, though to a much lesser extent, since the average number of mergers in the period of intense activity immediately following World War I exceeded the number during the comparable three-year period following World War II by only about one-quarter. The real significance of the current movement, which Dr. Kaplan neglects to point out, is that the increase in concentration resulting therefrom is superimposed upon an already extremely high level of concentration which, itself, is, in large part, the product of earlier merger movements.

5. Finally, in discussing what direct remedies are needed to meet this problem of the concentration of economic power, Dr. Kaplan is, for the most part, rather vague, indulging in such broad generalities as a recommendation that the antitrust laws be “recast into a consistent body of legislation” (p. 245), or that the antitrust agencies should “keep the channels of competition open” and “keep a watchful eye on the potential squeeze that integrated big business can apply to smaller independent units” (p. 217). This leaves the reader in the dark as to his attitude on such specific issues as the need for legislation to arrest merger activity, the desirability of implementing an effective dissolution program, the necessity of breaking up financial and corporate inter-relationships that eliminate competition, and other specific measures designed to arrest the growing concentration of economic power and prevent the complete extinction of the subject of this book.

Aside, however, from his treatment of this crucial subject of economic concentration, there can be little doubt that Dr. Kaplan’s book represents

the best general work yet written on the subject of small business. It should definitely be included among the supplemental readings in all courses in the fields of industrial organization, public control of business, and business finance.

JOHN M. BLAIR

Washington, D.C.

Problems in Price Control: Stabilization Subsidies. Pt. I, *Stabilization Subsidies, 1942-46*, by SEYMOUR E. HARRIS, Pt. II, *Wartime Subsidies and Food Price Stabilization*, by PHILIP RITZ. Edited by PETER G. FRANCK. Hist. Reports on War Admin., Office of Price Administration, Gen. Pub. No. 10. (Washington: Supt. Docs. 1948. Pp. xii, 241. 45c.)

The economist who wishes to form a judgment on the effectiveness of wartime stabilization subsidies will not find a completely satisfactory answer in this volume, but if he is willing to read through a good deal of overlapping and somewhat repetitious material, he will acquire a reasonably adequate idea of the various subsidy programs and the reasons for their adoption. The volume, which is one of the general series of Historical Reports on War Administration, would probably have been more readable had it been entirely the work of one author. While Professor Harris deals chiefly with the non-food subsidies and Mr. Ritz with the crucial role of food subsidies in holding down the cost of living, both authors devote considerable space to somewhat similar analyses of the general role of subsidies in the price stabilization program.

On the whole, Part II is considerably more informative than Part I, for its chronological form of presentation results in a systematic account of the evolution of subsidies from the early days of the defense program through the final breakdown of price control in the autumn of 1946. The political as well as the economic factors which led to shifts in policy are brought into the discussion in a highly illuminating manner. Part I, on the other hand, devotes a number of chapters to a classification and description of the various types of subsidies but makes little attempt to trace their history through the later years of the war and the immediate postwar period.

Both authors seem completely agreed that the subsidies which took the form of incentive payments to encourage high-cost marginal production were a decided success. In these cases, it was easy for OPA to demonstrate that the savings to both consumers and the Treasury far exceeded the cost of the subsidy, with the result that this type of subsidy aroused virtually no opposition. Much the same conclusion can be drawn, apparently, with respect to a number of programs in which government agencies absorbed losses in order to protect domestic price ceilings from the impact of various types of uncontrollable cost increases, especially those involving increases in war-risk insurance rates, shipping costs, and foreign sellers' prices. For many commodities, imports represented only a fraction of the total supply,

and the subsidies prevented the higher cost of the imported portion of the supply from forcing a break-through in the domestic price ceiling.

With respect to subsidies which were paid "across-the-board" (*i.e.*, to all dealers at some stage of production or distribution) the case is much less clearcut, although both Professor Harris and Mr. Ritz attempt to show that the savings resulting from such subsidies exceeded the cost. The net effects of programs of this type are far more difficult to analyze, especially when one attempts to take into account the probable indirect effects of averted price increases. As Mr. Ritz points out, the estimates presented by OPA experts in justification of such subsidies failed to draw a clear distinction between net savings to the Treasury and to the general public. Nor was any account taken of the higher tax revenues which would have accrued to the Treasury if prices had been allowed to rise.

Actually, it is doubtful if the case for across-the-board subsidies could ever be fully presented in statistical terms. When the subsidy program was substantially expanded in the spring of 1943, the basic consideration, as both authors suggest (though not, I think, with sufficient emphasis), was the possibility that a serious break in the price line would lead to a succession of wage and price increases which in the end might become uncontrollable. In the absence of subsidies, the price line could not have been held in a number of important cases without discouraging production.

The last word on the subsidy problem will certainly not have been written until a careful study is made under unofficial auspices. While there is no attempt to "white-wash" OPA in the present volume, it is none the less clear that an official history of this kind needs to be supplemented by a study which can consider fully and frankly such matters as interagency conflicts and the influence of changes in top OPA personnel. Such a study would be especially valuable if a comparison could be made with British and Canadian experience.

MARGARET S. GORDON

Berkeley, California

The Marketing of Surplus War Property. By JAMES ALLEN COOK. (Washington: Public Affairs Press. 1948. Pp. ix, 211. \$3.25.)

This is the first detailed report on the disposition of World War II surpluses to be published.

Of the approximate \$27 billion of property declared surplus, by late 1948 probably less than one-tenth remains in inventory. The surplus property disposed of includes industrial plants, aircraft, merchant ships, and capital and consumer goods. Dr. Cook describes the different disposal problems of each group and the difficulties and complexities within each group with two purposes in mind: first, to determine whether the shortcomings of the disposal program were legislative or administrative; and second, to recommend revisions of the law and policies or procedures of the War Assets Administration so that the disposal of the remaining surpluses will be more rapid. Unfortunately, about two years have already elapsed since

the major part of the report was completed in early 1947. It is worth while noting, however, that several of the major recommendations made by the author, both legislative and administrative, have already been put into practice.

Dr. Cook points out that many of the industrial plants to be sold were large in size, or "scrambled," or of no apparent civilian use, or poorly located (for civilian purposes). In view of these obstacles, it is obvious that the disposal rate would not be too rapid. He is, however, optimistic about the future disposal rate, particularly if the Congress enacts a "stand-by" program.

According to Dr. Cook, the Administration in the disposal of industrial plants contributed little in achieving one of many major objectives laid down by Congress, namely, "to discourage monopolistic practices and to strengthen and preserve the competitive position of small business concerns. . . ." He states that the country's 250 largest corporations secured about 70 per cent of all plant disposals (measured in terms of original cost).

The position of the War Assets Administration, illustrated in the case of aluminum plants, was that large competitors had already entered the industry. These entries apparently have not resulted in the infusion of a competitive spirit in the aluminum industry. The Department of Justice recently instituted action in the Federal Court requiring the Aluminum Company of America to divest itself of some of its property since the disposal of war plants had not established competitive conditions in the industry.

In the analysis of this problem, Dr. Cook accepts the Administration's statements, first, that it had no alternative in the disposal of industrial plants since Congressional policy was not specific enough; second, that the Department of Justice had the responsibility of approving the disposal of plants worth \$1 million or over; and finally, that the plants were large and could not be broken down. He fails to evaluate the problems and policies with a view toward determining the reality of the problems and the adequacy of the policies.

It seems to the reviewer* that the Administration could have met, at least in part, the Congressional mandate. For example, the Geneva Steel plant was sold to U. S. Steel rather than a new group. Here was an opportunity to add a competitor to an industry. Although I have heard officials of the War Assets Administration point out that there were no other responsible bidders, it seems to me that the Administration could have followed a positive policy by seeking out and assisting new firms.

Dr. Cook is not satisfied with the rate of disposal of consumer and producer goods. Here he has described and examined excuses rather than reasons. The major obstacle, in his opinion, was the priority system. There is no doubt that disposals would have been more rapid without it. (But if procedures delay the achievement of democratic objectives, we do not discard the objectives!) In the opinion of the reviewer the planning of a "pipeline of dis-

*The reviewer was employed by the War Assets Administration during 1944-1947.

posals" could have been developed so that there would have been a continuous, high disposal rate. A second obstacle, according to Dr. Cook, was inadequate sales planning. This, it seems to me, was the more serious obstacle. The reviewer recalls that when sales planning was instituted on a national level a "pipeline of disposals" was developed so that the rate of disposals reached a maximum in mid-1946. Sales declined subsequently not because of the decentralization of sales planning to the regional offices but the inability of regional personnel—consisting chiefly of salesmen—to plan. Incidentally, one office appointed an economist to be in charge of sales and the results were excellent.

A third obstacle to prompt liquidation, the author states, was the multiplicity of Congressional objectives. As evidence, he cites an interview with officials of the Richmond regional office. This is a case of excuse rather than reason. This office had probably the worst inventory records of any. It did not sell property because it did not know what it had to sell.

Dr. Cook not only fails to recognize the importance of correct inventory records but makes contradictory statements about it. He states that "an examination of inventory procedures in regional offices has revealed that inventories have been maintained and used daily" (p. 137) and that "the War Assets Administration has adopted an inventory control system which, by and large, embodies sound working principles" (p. 138). On the other hand, Dr. Cook reports that "the overall inadequacy of property descriptions has contributed one of the most serious obstacles to efficient sales operations" (p. 141).

Another pair of contradictory statements reflects the conflict not only in the minds of the officials of the War Assets Administration, but also in the mind of Dr. Cook, with respect to the primary objective in the disposal of surplus property. On one hand, the author states that the priority system "tended to divert War Assets' selling staffs from their primary objective—prompt liquidation" (p. 66). Yet he says that "liquidation should be the means to an end rather than the end in itself" (p. 77).

This book, in the opinion of the reviewer, fails to bring out in sharp focus the *major* issues of surplus disposal. No penetrating analysis is offered, for example, of the role of the military in handling a civilian job (there is a passing reference on this point on page 127) or the importance of planning on a broad scale. Dr. Cook has made the serious mistake of relying for his information on Congressional hearings and reports, which reflect political partisanship on the part of Congress and include defenses of operations of W.A.A. A second source is W.A.A. statements on policies and procedures. On the basis of the reviewer's observations (and this opinion was prevalent) any relationship between such statements and *actual* policies and procedures was purely coincidental. A third source was interviews with W.A.A. officials. Here, too, there is room for skepticism as to the accuracy of information. Only careful, persistent, and intensive investigation can dig out the facts about any government activity on the scale of that under consideration.

JACOB J. KAUFMAN

Public Utilities; Transportation; Communications

Electric Power and Government Policy. Factual findings by the Research Staff and the program by the Power Committee of the Twentieth Century Fund. (New York: Twentieth Century Fund. 1948. Pp. xx, 860. \$5.00.)

This book is devoted largely to the report of a competent research staff headed by Arthur R. Burns, the director, and Walter E. Caine, associate director. The research staff, each member of which presumably handled particular sections, consisted of Walter H. Beidatsch, Blanche Bernstein, Melvin G. de Chazeau, Hubert F. Havlik, C. Emery Troxel, Patricia Van Deraa, and William Vickrey. The project was designed to give an objective, factual picture of the electric power industry in its relation to government agencies. A preliminary summary of the main findings written by Edward Eyre Hunt was published by the Fund in 1944 under the title of *The Power Industry and the Public Interest*.

The factual content of this book supplements the theoretical and legal approach of recent and excellent public utility books. Interesting and significant information overflows into voluminous footnotes. If the book were nothing more than a handbook of statistics, its value would be considerably diminished by the fact that the material brought down only to 1940 is now outdated. The value of the book, however, springs more from the strong flavor of regulatory experience that permeates the discussion of every controversial problem.

An attempt is made to analyze some ten regulatory problems. The material is presented with caution and qualifications that would befit a study sponsored by a committee including Professor Bonbright, a farm leader, a regulatory lawyer and three power company executives. (The committee: J. Henry Scattergood, chairman, James C. Bonbright, LaRue Brown, Samuel Ferguson, Murray D. Lincoln, and Paul A. Schoellkopf.) Although the conclusions might conceivably represent a common meeting ground of the minds of the staff, they are so cautious and well guarded that it can be doubted whether many of them represent the strong beliefs of even one of the staff members. In short, the qualifications become the essence of the findings and thus it becomes difficult to summarize the contents.

The discussion of the legal framework of regulation is possibly best summed up by the staff's hope that the Supreme Court will now be disposed to give greater weight to commissions' findings of fact. It is worthy to note that this book is not unduly devoted to exorcising "dat old Debbil," *Smyth v. Ames*. For this, readers should be profoundly grateful. The study recognizes the importance of earnings-price ratios as one measure of a fair rate of return. The virtual failure of all commissions until recently and the complete failure of academic writers to consider this approach is almost inexplicable. It is a significant commentary on the solidity of this book to point out that a suggestion that commissions establish normal or average standards of costs of service to which utility companies should be held is relegated to a footnote (p. 105).

Presumably the appraisal of local, state and federal regulation did not yield results which could be stated in categorical fashion. On the basis of statistical studies, the staff reported that state-regulated utilities earned larger profits but had better rate records and lower expenses than locally regulated utilities. The report seems to doubt the efficacy of municipal competition or the threat of competition (pp. 243-5), although tables in the appendix seem to indicate otherwise where there is actual competition.

Now that the attempt has been made, it is to be doubted if much can be gained from a statistical comparison of rates or profits in some states with commission regulation as against selected states with local regulation. What is to be proved by lumping together rate or profit figures for California, Connecticut, Massachusetts, Michigan, New Jersey, New York and Wisconsin to determine the results of commission regulation as compared with local regulation, measured by results obtained in Florida, Mississippi, Minnesota and Texas? The substance of regulation is lost in statistics. One can well ask as to what extent results were influenced by peculiar operating conditions or financial histories, by special qualities of management, by public ownership movements, or political conditions. The effectiveness of commissions ebbs and flows; high tide and low water may both be reached within a few years; generalizations must be suspect.

So many reasons for variations are suggested that the report itself concludes that definitive conclusions are impossible. It would seem to have been to better purpose if the writers had gone further into another approach which was tried on a small scale—that of comparing various pairs of states. If the reasons for all variations could have been traced back to their origin, readers might well have more confidence in the conclusions. Such a task, however, was obviously beyond the time resources of the staff. Apparently much of the valuable information in the report was obtained from grass roots sources—interviews with regulatory officials—including among others those of California, Massachusetts, New York and Wisconsin, states generally recognized as being leaders in regulation.

The section on the financial organization of private systems is almost a text in corporation finance in itself. The discussion of problems of security regulation is particularly illuminating since all too often such discussions are confined to the more or less lifeless enumeration of rules and principles. The policy of the Securities and Exchange Commission emerges as one that has continuously evolved as experience accumulated. The treatment does remain, however, a treatment of problems rather than a recommendation of policy. Some objective standards such as the degree of overcapitalization, the proportion of debt, dividend arrearages and security flotations are considered. Commission regulation of security issues seems to have had some slight effect in reducing write-ups and dividend arrearages. The staff report concludes that state regulation of security issues has not necessarily failed but rather has not been tried (p. 275). Here again earnings-price ratios or yields might have been used as a means of evaluation.

The discussion of the problem of market area size may be summarized

with the statement that the report notes that state commissions have exercised little control over territorial markets, while the policies of both Congress and the Securities and Exchange Commission over a wider front lack clarity and consistency as well as detail. The treatment is critical and descriptive, but there are no concrete recommendations of policy.

The study contains carefully qualified conclusions on municipal ownership presented against a thorough-going discussion of the many pitfalls encountered in making valid comparisons. It is pointed out (p. 435) that the major economies of municipal ownership arise from lower capital costs, more conservative valuation of assets and lower operating expenses. It is believed, with some evidence to the contrary, that tax advantages are offset by contributions to municipalities. These conclusions are based upon the many studies of the problem that have appeared in the past rather than upon new investigations. The report might have been strengthened by a thorough, objective analysis of the Ontario Hydro Commission, something that is sadly needed. The study of rural electrification may be summarized by the guarded conclusions of the report that "This survey has indicated little direct federal subsidy to rural cooperatives. . . . It may or may not be desirable to subsidize rural electrification, either for its own sake or, in times of depression, to contribute toward recovery" (p. 479).

The treatment of the subject of municipal ownership fails, along with every other treatment with which the writer is familiar, in that only after long study can even an expert reader evaluate the significance of isolated blocks of statistics treating various aspects of the problem. Why not utilize the device of hypothetical models of private and publicly owned utilities, incurring representative expenses with representative rates applied to similar rate groups? The specific effect of taxes, operating expenses, etc. could be traced down to their final incidence upon rates. The reader would be given quantitative answers to many of his questions without further research while partisans would have a definite starting point from which to begin their wrangling. The assumptions would of necessity have to be made with care but this staff should have the competence to make them.

The study affords us no definitive answer to the major question of public policy towards the giant multiple-purpose projects. The yardstick idea is firmly eschewed, the lack of consistent policy between the projects is decried, and Congress is called upon to lay down at least the major outlines of power policy. But we are left in the dark as to what they should be. It is taken for granted that indirect competition between private and public ownership should and will continue, but no direct attempt is made to grapple with the problems raised by the obviously cumulative growth of public ownership that we find today. The importance of the projects as a means of business cycle control is recognized.

The study concludes with a discussion of the objectives of a national power system, the power committee's report and recommendations and a statistical appendix. The committee's report is even more cautious than the main body of the report. Professor Bonbright, with hard-headed perversity, takes

frequent exception to the conclusions. In one instance dissents are registered by both Bonbright and Samuel Ferguson (in respect to divorcing gas and electric properties). Needless to say, they are not in agreement.

Although the book is notably free from excursions into the fields of high theory, the report and recommendations take notice of the arguments against taxing a decreasing cost industry. The efficacy of tax reductions in the light of ineffective regulation is questioned by Professor Bonbright (p. 746). Few can disagree with the stated objectives of (1) a workable system of regulation and (2) the proper coordination of government and private ownership (p. 748). We may be approaching the former, but the reviewer agrees with the report in that we get about the kind of regulation we deserve (p. 754). To achieve the second objective the report tentatively suggests a type of power organization similar to the British Grid and the Ontario Hydro. Much is to be said for the proposal although it is difficult to see how coordination is to be obtained as long as governmental ownership remains as such a dynamic institution. There is a plea that negotiational rate making be brought out into the public view (p. 759).

There are no unqualified answers to controversial questions. This is probably all to the good. Instead one finds some cautious recommendations and a thoroughgoing discussion of the qualifying factors. It is this wealth of minutia pertaining to the industry and to regulation that makes this book a valuable one to the student or to framers of policy. No one contemplating further research in the field would be justified in neglecting a preliminary reading of this book.

E. W. CLEMENS

University of Maryland

The Regulation of Railroad Abandonments. By CHARLES R. CHERINGTON. (Cambridge: Harvard Univ. Press. 1948. Pp. x, 277. \$4.00.)

In undertaking this study, the author had in mind two objectives. The first was that of a detailed survey of the policies of the Interstate Commerce Commission in respect to the problem of railroad abandonment, over which the Commission was given control in 1920. The second was the development from this experience of any general conclusions which it might offer in respect to techniques of administrative regulation.

Two sections of the book contain excellent discussions of complicated problems dealing respectively, with judicial review and with actual Commission policy in sanctioning or denying abandonments. Of equal quality but of lesser importance are the discussions of the legislative background of the abandonment clause and Commission procedure in handling the cases.

The critique of the Commission policies, and the treatment of the implications which the Commission action offers for administrative regulation in general are much less satisfactory than the descriptive material. The ultimate conclusion—that a Bureau of Coordination and Research should be established within the Commission (and similar bureaus in other regulatory agencies) for purposes of long-range planning and evaluation of the effects

of particular Commission actions in terms of the plans developed—is one with which there can be substantial agreement. And, in a sense, the failure of the Commission to enunciate a clear policy in respect to abandonment may be advanced as justification for such an agency. But I am not at all sure that the actual decisions of the Commission would have been very different had long-range considerations been taken into account, as the author maintains. Professor Cherington is very critical of the particularist approach of the Commission—that is, of the tendency to deal with each case as a separate problem, with an attempt to balance conflicting considerations involved in the particular case—and condemns the Commission for failing to adopt a “planned coherent regulatory strategy.” He is likewise critical of the Commission for being unnecessarily restrictive in preventing abandonments which the carriers would like to make. But his criticism of the Commission on these bases is greatly weakened by the failure to advance, or even to indicate by implication, what “planned strategy” would involve, or what general principle the Commission should have followed in regard to abandonment.

The establishment and utilization of such a principle is not an easy task. The old view, one still accepted by many, that any line on which costs are not covered (granted a reasonable basis for allocating costs and revenue to a particular line) should be abandoned has been seriously questioned by the marginal approach to utility operation and pricing. There may be, and probably are, cases in which the losses to the shippers from abandonment will exceed the losses on the line from continued operation; retention of the lines is justified and practicable (under what amounts to a type of recapture policy) in cases in which the road as a whole is earning more than a necessary return. And essentially—without stating the principle in so many words—the Commission has been attempting to weigh these conflicting considerations of carrier and shipper losses. It is doubtful if a more precise statement of principle would be of much assistance; there is no possibility of calculating exactly the loss to the community from abandonment, or, for that matter, the exact loss from operation of the particular branch. The best that can be hoped for is a rough weighing of the two considerations. The fact that a railroad can never be sure in advance whether the Commission will allow a particular abandonment is an inevitable product of the difficult nature of the problem, rather than a product of the Commission's past policy, as the author argues. In general, Professor Cherington has not established a strong case that Commission policies in abandonment cases demonstrate a fundamental weakness in the structure and operation of the Commission.

The section dealing with the causes of abandonment is not entirely adequate. The author's listing of the causes of traffic declines is an improvement over previous attempts, but stops short of a fundamental problem, the answer to which is not always entirely obvious: exactly why, and under what conditions will a traffic decline cause losses and result in abandonment? Further attention is needed to the question of the carriers' own policies in

regard to seeking abandonment. One legal question which might have been raised is that of the relative powers of the Commission and the federal courts in the case of abandonment of bankrupt lines, an issue which arose in the *Salt Lake and Utah* case and is likely to arise in the future in others.

This book represents a worthwhile contribution to the field of study of administrative regulation, one whose usefulness is enhanced by the excellent style of writing. But it is by no means a complete study of the railroad abandonment problem, from the standpoint of economic welfare considerations involved. It should be pointed out that the author's primary interest is in the field of political science, not economics. But there remains the fact that the author has undertaken to criticize the Commission's policies upon the basis of economic criteria without making clear what the latter are.

University of Illinois

Land Economics; Agricultural Economics; Economic Geography

Road to Survival. By WILLIAM VOGT. (New York: William Sloane Associates. 1948. Pp. xvi, 335. \$4.00.)

Our Plundered Planet. By FAIRFIELD OSBORN. (Boston: Little Brown. 1948. Pp. xiv, 217. \$2.50.)

These two books bring vividly to the attention of hundreds of thousands of readers significant trends and problems regarding the nation's and world's natural resources. The books come on a wave of public interest in conservation and rebuilding of our diminishing resources. In part they have made the wave. Each has been selected by a popular book club.

The tremendously accelerated wartime drain on world resources followed by the dramatic presentation of the economic reconstruction needs of the western European democracies and our own role in providing aid have sharpened our awareness of the resources problem. Man's ultimate dependence on his environment of soil, water, and plant and animal life for his daily living and future well-being is clearly depicted by both Osborn and Vogt. Not since the heyday of Theodore Roosevelt and Gifford Pinchot have these issues been so much in the public eye. Frequently these two books have been referred to as "scare" books. What they point out should not scare us. Rather it should sting us into more vigorous conservation efforts. The authors have performed a public service in focusing public attention on the need for conservation.

Neither Vogt nor Osborn is primarily an economist or, indeed a social scientist of any kind. A prominent ornithologist, Mr. Vogt is now chief of the Conservation Section of the Pan-American Union in which position he has had broad experience in studying population and resources problems in various Latin American countries. Mr. Osborn is president of the New York Zoological Society. Of the two books, Osborn's is the smoother, more balanced, and less likely to arouse violent emotional reactions for or against. Vogt's book is uneven, written at white heat, and full of fight. It contains

sweeping scientific, cultural, ethical, and economic generalizations and predictions, sometimes without satisfactory backing. Fortified with great quantities of notes, observations, and impressions, Vogt has lunged into his subject matter with both arms swinging. An economist or scientist could easily be unfair in appraising this book.

The main propositions of each book are similar. Following Vogt's more extreme presentation, the whole business may be summed up in the equation $c = b : e$. The carrying capacity (c) of a piece of land (or a nation or the world) at any time varies directly with its biotic potential (b) and indirectly with the environmental resistance (e). An improvement in land use such as better crop rotation or the application of needed fertilizer may increase crop yield and hence the biotic potential and carrying capacity. Soil erosion or leaching will increase environmental resistance, reduce the biotic potential, and thus lower carrying capacity. The elements in this relationship change, but for the impending future, Vogt argues, we may expect e to increase, b to decrease, and c to go down and down. Coupled with this, Vogt sees a century and more of increasing population in most countries. The rising population curve will cross the falling carrying capacity curve, leaving mankind to gloom and misery everywhere.

The situation may, however, be rescued by strenuous, intelligent, worldwide action on two fronts. We must conserve and build up our soil and we must stop having so many babies. Both Vogt and Osborn agree upon the need for resources conservation and development. Vogt goes far beyond Osborn in calling for a reduction in population. Vogt would withhold United States aid to Greece and China until those countries take actions to check births. In his opinion, one hundred million Americans would be about right; that is, would be the optimum population for a sustainable ecological balance in nature. One observer interpreted Vogt as saying, "Forty-five million Americans, drop dead!"

The form of the two books is similar. First is a series of chapters developing the background and stating the main propositions. Following are chapters dealing with the resources trends and critical problems in the different continents and countries. The promising as well as the inadequate efforts toward conservation are discussed.

Since the appearance of these books, scientists of many stripes have stepped forth to condemn them. Many soil scientists say that the term "natural balance" is meaningless apart from man's own cultural achievements in soil science, engineering, and economics. They maintain man's efficiency in food production and distribution is probably still accelerating. Enough tillable but at present unused land remains in the tropics and other areas to produce food for an adequate diet, as determined by the United Nations Food and Agriculture Organization, for the whole world by 1960. In addition, the biotic potential of various types of soil may increase greatly as knowledge and practice improve.

Population experts point to the fact that in the more advanced industrial areas net reproduction rates have decreased, in many instances below the

rate required for replacement. Motivations and techniques for limiting the size of families may be expected to become increasingly important. Men do not obey rigid laws of increase like so many fruit flies. World population may increase for another century or so, and then hold steady or even decrease.

Of the two authors, Vogt especially has little use for economists, unless they are Physiocrats. "Purchasing power goes back fundamentally to natural resources—especially the land—and no amount of symbolical juggling can help us to escape that hard fact" (p. 78). For Vogt the source of wealth is land, especially wheat land. Industrialization, notwithstanding the remarkable increase in *per capita* real income that has come in its wake, is presented as a "fallacy."

In another purple passage Vogt writes: "One of the chief causes of our ecological imbalance is our economic thinking. We identify the symbolic dollar with real wealth. . . . We extract oil, iron ore, and fine timber, and canvasbacks, and call it production . . ." (p. 146). He then calls for subordination of the "money evaluation of the exploitative lumberman, farmer, stockman, trapper, and industrialist . . . to a biophysical evaluation." At other points in the book, the free enterprise and profit system is condemned in harshest terms. Economic thinking is presented as the narrowest kind of "quick profits and the devil take the hindmost" doctrine.

Osborn is more temperate. Having in mind the continuing attack of the cattle and sheep interests on the federal forests, parks, and grazing lands in the West, he concludes ". . . the profit motive, if carried to the extreme, has one certain result—the ultimate death of the land" (p. 183). Osborn, however, does not make any blanket condemnation of the free enterprise system.

The important element of truth in Vogt's diatribe is that more economists should take the long view, giving greater weight to future consequences of present actions. The need for living with nature both now and in future generations should enter the value scales of the economist as well as of the farmer, stockman, fisherman, and industrialist. There is, of course, nothing in economic theory to exclude such considerations. Economic theory as such does not require that the future be discounted at any specified rate. That other scientists, and possibly the general public as well, do not realize this points to a shortcoming of the economics profession in the matter of public information which cannot be dodged.

It must be admitted also that there is need for a further working of general economic theory to cover more adequately the field of resources conservation and development. What seems to be required is not a new structure but rather an extension and adaptation of the present structure to give the additional material more relevance. Production theory as taught in most economics courses, for instance, is focused on the business firm, usually a manufacturing firm, which purchases materials and hires labor in order to turn out a product. Economists should give more attention to the national production which would result from better land and water use and sustained yield forestry. Such programs also require an economizing of scarce re-

sources, but in terms of social as well as firm and individual considerations.

Perhaps one reason why conservation policies sometimes appear confused and contradictory and do not have effective public support is the failure so far to relate conservation economics broadly to economic theory. More than this, minerals conservation, land conservation, and water conservation are not related to one another closely enough. The division is especially sharp between the conservation of exhaustible and inexhaustible resources. Perhaps the greatest contribution the economist can now make is to bring these different subjects in out of the rain and put them securely under the one tent of economic theory.

It cannot be denied that these two books do point to fundamental dangers and needs frequently neglected or underestimated. The need for better conservation of natural resources is so widespread and so urgent that an appeal to emotion is desirable. Otherwise, we may be both too little and too late with strong actions for the protection and improvement of our resources base. Professional economists should keep this in mind when they present their criticisms of the case made by such writers as Osborn and Vogt.

JOSEPH L. FISHER

Washington, D.C.

Introduction to Agricultural Prices. By WARREN C. WAITE and HARRY C. TRELOCAN. (Minneapolis: Burgess Publishing Co. 1948. Pp. iii, 227. \$4.00.)

This text is primarily concerned with price variations that are important for entrepreneurial decisions in agricultural production and marketing. It is organized by economic concepts rather than by commodities (but 20 index entries can be found under "wheat"). However, the authors undertake no rigorous logical development of theory. Rather, they assemble a selection of practical analytical tools and show the student how to use them for understanding and dealing with marketing problems.

After a review of the nature of money and prices, the book discusses demand, supply, and competitive and monopolistic price determination. There follows an extensive treatment of market organization and structure and price-making processes, of transfer costs and other locational influences, of seasonal variation, and of quality variation. A substantial chapter is included on futures trading, and one on prices of the factors of agricultural production.

Some main statistical techniques are brought together in a later chapter of the book and in appendices. Here, again, a kit of tools is assembled with practical instruction in their use rather than a rigorous mathematical development.

Two things in the book deserve special commendation. One is the extensive use of tabular and graphic materials from actual research studies. Scarcely a page lacks illustration of this type, much of it reflecting considerable work by the authors in adapting materials to the textual analysis. The student

receives both a wide sampling of available source materials and a practical experience in their interpretation and use.

Second is the emphasis upon evaluation rather than mere description. The book concludes with a chapter appraising our wartime experience with price control and another analyzing farm price-support programs, past and proposed. But throughout the book, whether discussing cyclical changes, monopolistic practices, cooperatives, government marketing programs, or futures trading, the authors call the student's attention to consequences for different groups in society, and to over-all social implications. They take time to refute the doctrine that changes in farm income produce seven-fold changes in national income. They risk a reasoned forecast of a short-run downward adjustment of agricultural prices relative to nonagricultural, followed by a secular decline—or at best a stable relationship—over the next quarter century. Regardless of whether one agrees with the author's opinions, this reviewer believes that it is good for students to have issues important for policy brought out for class discussion.

The book fills an important need in the current shortage of analytical, as versus merely descriptive, texts on agricultural marketing. There is merit in its practical approach. The limitations of that approach might be partly offset by adding references to sources of more rigorous development of the analytical concepts used, both economic and statistical.

HERMAN M. SOUTHWORTH

Washington, D.C.

Labor

Contemporary Unionism in the United States. By CLYDE E. DANKERT. (New York: Prentice-Hall, 1948. Pp. xv, 521. \$5.00.)

The above volume is a useful handbook on labor unions. In twenty-seven chapters, the author has discussed every aspect of unionism from its history to its effect on the general welfare. Most of the time his material is limited to describing known facts. Occasionally his observations are not too meaningful. For example, in a footnote we are told that since workers in the Soviet Union supply all capital, they do "not have to worry about their 'share' since presumably, everything goes to them anyway." Do they or do they not have to worry, and why? Does everything go to them, and what is everything? He then draws the conclusion that trade unions of the type to which we are accustomed are not needed. This, of course, means that there are no problems of income allocation in the Soviet Union, and that there are not even any bases for complaints. Actually, capital in the Soviet Union is supplied by the community by not consuming its total income in a period. Has the worker no interest in deciding on the amounts to be consumed and saved? If reports from the Soviet Union can be believed, the Russians need unions like our own very badly. If our type of unions existed, there might be a few more consumption goods available. All the author has really said is that a totalitarian regime has no place for free unions.

The discussion of "voluntarism" leaves out the influence of government policy upon this attitude. Between the 1880's and the early 1930's, government intervention would have meant mostly stronger government action against labor. Nor is the A. F. of L.'s change of view on this point dealt with adequately. This discussion illustrates a serious defect in this volume, the failure to pursue a topic adequately. While it is true the "Federation realizes now that gains that are extremely valuable to labor may be achieved not only through collective bargaining but also by legislation," we ought to be given some explanation for the change in attitude. What is "a rigid adherence to the Gompers philosophy of voluntarism" in politics? Actually, there is slight difference except as to scale of activity between Gompers' and the present policy.

In discussing the government of the A. F. of L., Professor Dankert agrees that "unity in the executive council is not as real today as it was under the regime of Gompers." This may be true, but it may be well to point out also that the A. F. of L. is more united today than it was in Gompers' day. No appreciable socialist faction exists today, as it did from the beginning of the A. F. of L. to the 1920's. The discussion of the attitude of the A. F. of L. toward joining the World Federation of Trade Unions leaves much to be desired, and the impression is given that the objection is primarily based upon the A. F. of L.'s espousal of "free enterprise." But the A. F. of L. has more substantial objections. English unions are also opposed to "free enterprise," and the A. F. of L. maintains cordial relations with them. English unions can, however, adopt any policy they choose, whether it be favored or opposed by the government. The Russians cannot. Why meet with the Russian unions, they cannot act independently.

This volume has many merits, and it is a usable text in courses on trade unionism. Its greatest shortcoming is the failure to carry through in discussion of issues. Many times the points are given for and against a particular view, but the question is not examined beyond the point of stating the issues. It is frequently more desirable to err, especially if the error is suggestive, than to allow a question to remain "up in the air." Consequently, a teacher will have to be ever watchful to supplement the material. Labor problems of various kinds can be illuminated by different types of analysis, but some explanation beyond stating that groups prefer different alternatives is essential if a volume is to be more than a mere handbook.

PHILIP TAFT

Brown University

Industry-wide Bargaining. By LEO WOLMAN. (Irvington-on-Hudson, N.Y.: The Foundation for Economic Education. 1948. Pp. 63.)

In this pamphlet a member of the National Bureau of Economic Research undertakes to prove that industry-wide bargaining is dangerous. Though the best examples of such bargaining are in coal mining and on the railroads, he is sound in adding industries like steel and automobiles where the contracts are fairly uniform. Regional examples are also given.

The indictment is based on the premises that national unions generally have strong centralized power over both locals and individual members (pp. 18, 52), that national unions are essentially monopolistic (p. 25 ff.), and that their specific goal is uniformity (p. 9) that will remove labor conditions from the field of competition (p. 21). From these premises the author concludes that agreements reached in industry-wide bargaining do stop such competition both within an industry and among industries (p. 22) and even "will amount in time to taking business out of competition" (p. 33).

To this, he adds criticisms of the increased costs (railroads and coal, pp. 36-38), of the general inflexibility of labor costs so that management cannot adjust to changing conditions (p. 38), and of the practice of employers' associations joining with unions "in fixing costs and prices" (p. 42).

Nowhere is there a suggestion of possible advantages from industry-wide bargaining. The balance of the pamphlet cites examples of the above arguments, some distorted labor history, apologies that have been made for union "monopoly," and of course a remedy. This remedy is mainly to apply the antitrust laws rigidly to labor organizations (p. 62), though strengthening of independent ("company") unions is expected to help (pp. 47-48, 61).

In such a study one may separately examine both premises and reasoning, and also extraneous arguments. It may, for instance, be questioned whether national unions *generally* have the power imputed to them. On the other hand, there seems nothing to gain in quibbling over an exact definition of "monopoly" as applied to labor organizations (unless it is used for derogatory effect), though we may ask whether labor monopolies actually "overshadow any private business monopolies" (p. 33).

That industry-wide bargaining does largely remove labor conditions from competition within an industry may be granted. But only where a single union is powerful in related industries is it effective between industries. For the immediate future it appears unlikely that even within either of the great federations there will be enough collusion among unions to achieve this end. No evidence is offered that business will be taken out of competition (even regionally), so one can merely accept or disagree with the statement, not with the absent reasoning.

The added criticisms are also questionable. Has it been only, or even mainly, the labor costs of railroads and coal mining that have caused branch lines to cease operating and coal consumers to switch to other fuels? Accepting a relationship, other items may also be admitted. Though on page 54 the author states that "no satisfactory evidence is at hand" to show that restriction of output is limited to craft unions, he himself adduces none to show that the union rules with "the most costly effects" are these restrictions. Nor is there evidence for his statement on the opposite page that before 1935 unorganized employees prevented these restrictions from being effective. (Surely Mathewson's *Restriction of Output Among Unorganized Workers* has shown the contrary.)

The inflexibility (except upward) of labor costs does indeed merit serious consideration. If the economy cannot or will not be stabilized, management needs to be able to make an adjustment in costs. But it has yet to be shown

why the burden of this adjustment should be placed mainly on labor. The estimate (p. 31) that wages and salaries amount to almost 80 per cent of the national income does not seem born out by government statistics, nor does it seem relevant to the problems of a firm that can adjust only its own labor costs, not those included in the prices it pays for raw materials and capital goods.

No doubt there are many undiscovered and unprosecuted cases of employers (and employers' associations) fixing prices in collusion with unions; no doubt the possibility is ever present. But that it is yet a common practice is dubious.

History is most useful when it is not distorted. In consideration of the way company unions flocked to join the AFL unions prior to 1935 when the NLRB started aiding the latter, should one agree that company unions were a real barrier to other unions (pp. 47-48)? Is it wholly correct to state that since 1914 unions have been immune to the antitrust laws (p. 62)? Should we also agree that the antitrust laws have so far prevented monopolies other than labor (as the author implies on the same page)?

Perhaps the pot has no right to call the kettle black. Perhaps it is irrelevant that business policies in large firms are no more decided democratically by stockholders than union policies are by union members—usually less. Yet a recognition of this source of difficulties in labor relations might help the reader. Unions feel they must be large to take on large employers; then they are too large for small employers. To be fair to both sides, since an effective prohibition of industry-wide bargaining can be achieved only by reducing the size of unions, the employers too must be curtailed. Are we willing to do so?

And is the uniformity of working conditions so intolerable an evil? Classical economics would seem to allow standardization in a stable economy. Under changing conditions such forced standardization would hasten the natural tendency and more quickly slough off sub-marginal producers. Has the growth of uniformly improved conditions unstabilized the coal industry compared with the 'twenties and early 'thirties? Is organized labor more restrictive than the vested interests of business? Do unions affect prices more than the imperfections of competition under oligopoly? In so one-sided a discussion as Wolman's, we are not likely to find an answer.

H. FABIAN UNDERHILL

Indiana University

Wages. By MAURICE DOBB. (London: Nisbet & Co., Ltd. New ed. 1946. Pp. ix, 222. 6 s.)

In this revision, the central chapters on "Theories of Wages" and "Wages and Bargaining-Power" have been altered considerably and the other chapters have been brought up to date.

The book is well written, the treatment is balanced, and the conclusions are sensible. The discussion of methods of wage payment is especially clear and acute.

The author's position with respect to wage theory may be characterized as a healthy scepticism of traditional theories without too much to offer in

their place. As a realist, he repeatedly points out that relationships between wages and other economic variables are much more complex than was formerly supposed. Influenced by Keynesian developments, doubts are expressed concerning "the simple notion of some kind of elastic demand-schedule for labour." With respect to wage differentials between occupations, Mr. Dobb finds that actual differences are so much in conflict with the principle of "equality of net advantages" as "to incline one to think that it cannot be an explanation at all of the major differences of wages in our present wage-system."

A "handbook" cannot be criticized for failing to be a learned and complete treatise. This book does accomplish the purposes of the author. Its most noticeable weaknesses are in areas that have received considerable attention in this country during the postwar period, namely, geographical differentials, the influence of unions on wages, the issue of "labor monopoly," the economics of minimum wages, and the question of a "national wages policy." The issue of "labor monopoly," for example, is not even considered although employer monopoly is, and no systematic treatment is given to the influence of unions on wage structures and wage levels or the economic justification for minimum wage legislation.

An adequate theory of wages must stem from an understanding of wage and employment practices in the absence of unions. An analysis of non-union conditions must provide the sound economic support for labor-standards legislation. Mr. Dobb fails to contribute to such understanding and support when he refers repeatedly to "the labour market" (without indicating what kind of a "market" he conceives it to be), and to "the 'normal' competitive wage." Studies of employment practices and wage structures and policies under non-union conditions show such notions to be misleading and unrealistic. The notion of an existing "competitive wage" is certainly chimerical, yet some American economists still seek to define labor monopoly in terms of a "competitive level of wages" and to classify individual wage rates or wage increases as either "competitive" or "monopolistic." Why let facts spoil a beautiful theory?

In the last chapter, the question of "some sort of centrally co-ordinated wage-policy, worked out between the Government and the trade unions at a high level" is discussed briefly but without shedding any new light on the matter. It is to be hoped that experience then available, will permit the author to expand on this subject in the next revision. The extent to which the spread of collective bargaining and the political compulsions in national unions will give our economy an inflationary bias during the next decades is a problem that needs careful analysis. Any solutions that England can develop to the conflict between national policy-making or planning and free trade unionism with autonomous unions should be helpful to us in working through the wage-price difficulties that exist under free collective bargaining in a full employment economy.

RICHARD A. LESTER

Princeton University

TITLES OF NEW BOOKS

Economic Theory; General Economics

ALLEN, G. C. *Economic thought and industrial policy*. (London: H. K. Lewis & Co. 1948. Pp. 18, 2s., 6d.)

An inaugural lecture at the University of London, Professor Allen reviews the difficulties of administering a half-planned economy in conformity with the requirements of technical innovation and enterprise in developing a progressive industrial structure. He weighs the balance toward less planning and more enterprise.

BENTHAM, J. *A fragment on government and an introduction to the principles of morals and legislation*. Edited with an introduction by W. Harrison. (New York: Macmillan. Oxford: Basil Blackwell. 1948. Pp. lxvii, 435. \$2.25.)

BODDY, F. M., editor. *Applied economic analysis*. (New York: Pitman Pub. Corp. 1949. Pp. xvi, 573.)

Other contributors are F. E. Childs, W. R. Smith, O. H. Brownlee, A. E. Coons, V. Salera.

BOWEN, E. E. *Economics simplified*. Revision edited by G. L. Rusby. (New York: Robert Schalkenbach Foundation. 1948. Pp. x, 234.)

A restatement of the single tax position.

BROWN, E. H. P. *The framework of the pricing system*. (Lawrence: Univ. of Kansas Student Union Book Store. 1949. Pp. xvi, 221, \$3.25.)

An elementary guide to price analysis, first printed in England in 1938.

DEMPSEY, B. W. *Interest and usury*. (London: Dennis Dobson. 1948. Pp. x, 233. 12s., 6d.)

Two new chapters cover the principal developments of the past seven years.

FELDMAN, G. J. and ZORN, B. A. *Robinson-Patman act; advertising and promotional allowances; what you must do, how the law applies, what the authorities have said.* (Washington: Bur. of Nat. Affairs. 1948. Pp. 296. \$5.)

FULLER, D. R. *Government financing of private enterprise.* (Stanford: Stanford Univ. Press. 1949. Pp. ix, 206. \$3.)

GEORGE, E. B., SAWYER, A. E., EDWARDS, C. D., SIMON, W. *Basing points: a symposium.* Current bus. stud., no. 1. (New York: Institute of Trade and Commerce Professions. 1948. Pp. 51.)

GRIFFIN, C. E. *Enterprise in a free society.* (Chicago: Richard D. Irwin. 1949. Pp. xiv, 583. \$5.)

HIBBEN, T. and PICO, R. *Industrial development of Puerto Rico and the Virgin Islands of the United States—a report of the United States section, Caribbean Commission, July, 1948.* (New York: Columbia Univ. Press. 1948. Pp. 320. \$1.50.)

MACHLUP, F. *The basing-point system—an economic analysis of a controversial pricing practice.* (Philadelphia: Blakiston. 1949. Pp. vii, 275. \$5.)

MILLER, J. P. *Pricing of military procurements.* Stud. in nat. policy no. 2. (New Haven: Yale Univ. Press. London: Geoffrey Cumberlege. 1949. Pp. x, 292. \$4.)

NOVICK, D., ANSHEN, M. and TRUPPNER, W. C. *Wartime production controls.* (New York: Columbia Univ. Press. 1949. Pp. vi, 441. \$6.)

PEGRUM, D. F. *The regulation of industry.* (Chicago: Richard D. Irwin. 1949. Pp. xii, 497. \$4.75.)

SOVANI, N. V., editor. *Reports of the Community Prices Board.* Pub. no. 20. (Poona: Gokhale Inst. Pol. and Econ. 1948. Pp. xv, 238. Rs. 10; 15s.)

TOMPKINS, D. C. *Materials for the study of federal government.* (Chicago: Pub. Admin. Service. 1948. Pp. 338.)

Annual report of the Select Committee on Small Business, 80th Cong., 2d sess., pursuant to H. Res. 18, 80th Cong., 1st sess., Dec. 29, 1948. (Washington: Supt. Docs. 1948. Pp. 37.)

- Commodity transactions. Hearings, House committee to investigate commodity transactions, 80th Cong., 2d sess., March 1-June 16, 1948.* (Washington: Supt. Docs. 1949. Pp. 631.)
- Delivered pricing and the law.* Prepared by the Committee on Economic Policy. (Washington: Chamber of Commerce of U.S. 1948. Pp. 27.)
- Extension of voluntary controls agreement. Hearings, Subcommittee on Small Business, 81st Cong., 1st sess., on S. 547, January 25, 1949.* (Washington: Supt. Docs. 1949.)
- Government and industry—a survey of machinery for consultation and cooperation.* (London: H. M. Stat. Office. 1948. Pp. 32. 9 d.)
- Monopolistic and unfair trade practices. Hearings, subcommittee House Select Committee on Small Business, 80th Cong., 2d sess., September 3-November 24, 1948.* (Washington: Supt. Docs. 1949. Pp. 1368.)
- Monopolistic and unfair trade practices. Report of the Select Committee on Small Business, 80th Cong., 2d sess., December 29, 1948.* (Washington: Supt. Docs. 1948. Pp. 33.)
- A national oil policy for the United States—a report of the National Petroleum Council.* (Washington: Nat. Petroleum Council. 1949. Pp. 23.)
- The national stockpile; a non-confidential supplement to the stockpiling report, July 23, 1948. U. S. Munitions Board.* (Washington: Supt. Docs. 1948. Pp. 20.)
- Report of the Federal Trade Commission on the merger movement; a summary report.* (Washington: Supt. Docs. 1948. Pp. 134.)
- The state of food and agriculture—1948; a survey of world conditions and prospects.* U.N. Food and Agric. Organization pub. (New York: Columbia Univ. Press. 1948. Pp. 222. \$2.)

Public Utilities; Transportation; Communications

- HULTGREN, T. *American transportation in prosperity and depression.* Stud. in bus. cycles, no. 3. (New York: Nat. Bur. of Econ. Research. 1948. Pp. xxxiii, 394. \$5.)
- WALKER, G. *Road and rail—An enquiry into the economics of completion and state control.* 2nd ed. (London: Allen and Unwin Ltd. New York: Macmillan. 1949. Pp. 282. \$3.75.)
- This issue is unchanged from the English issue of 1947.
- Domestic air cargo.* (Washington: Civil Aeronautics Admin., Dept. of Commerce. 1948. Pp. 56.)
- Final report of the Select Committee to Investigate the Federal Communications Commission, pursuant to H. Res. 691, January 3, 1949.* (Washington: Supt. Docs. 1949. Pp. 27.)
- Interregional highways.* (Washington: Supt. Docs. 1944. Pp. 184. 75c.)
- Interstate Commerce Commission 62d annual report, November, 1948.* (Washington: Supt. Docs. 1949. Pp. iv, 186. 35c; cloth, \$1.)
- Railroad transportation—a statistical record, 1911-1947.* (Washington: Assoc. of American Railroads, Bur. of Railway Econ. 1948.)
- Second national electric power survey.* (Washington: Nat. Security Resources Board. 1948. Pp. 51.)

Industry Studies

- GOODMAN, C. S. *The location of fashion industries, with special reference to the California apparel market.* Michigan bus. stud. vol. x, no. 2. (Ann Arbor: Univ. of Michigan School of Bus. Admin. 1948. Pp. 105. \$2.)
- KNOWLTON, E. H. *Pepperell's progress—history of a cotton textile company, 1844-1945.* Harvard stud. in bus. hist. xiii. (Cambridge: Harvard Univ. Press. 1948. Pp. xxix, 511. \$5.)

- MACLAURIN, W. R., with R. J. HARMAN, technical assistant. *Invention and innovation in the radio industry*. (New York: Macmillan. 1949. Pp. xxi, 304. \$6.)
- SCHLEEF, M. L. *Manufacturing trends in the inland empire*. Econ. and bus. stud. bull. no. 4. (Pullman: State College of Washington Bur. of Econ. and Bus. Research. 1947. Pp. xxii, 91.)
- STEWART, J. R. *Japan's textile industry*. (New York: Inst. Pacific Relations. Pp. iv, 82. \$1.25.)
- Changes in distribution of steel, 1940-1947. Special report of the subcommittee, Senate Special Committee to Study Problems of American Small Business, 80th Cong., 2d sess., pursuant to S. Res. 20, February 10, 1949.* (Washington: Supt. Docs. 1949. Pp. 49.)
- Steel supply and distribution problems. Final report of the subcommittee, Senate Special Committee to Study Problems of American Small Business, 80th Cong., 2d sess. pursuant to S. Res. 20, February 10, 1949.* (Washington: Supt. Docs. 1949. Pp. 79.)

Land Economics; Agricultural Economics; Economic Geography

- BOGART, E. L. *Peacham—the story of a Vermont hill town*. (Montpelier: Vermont Historical Soc. 1948. Pp. 494. \$6.)
- CARVER, H. *Houses for Canadians*. (Toronto: Univ. of Toronto Press. 1949. Pp. xiv, 156. \$2.50.)
- FRIEDLANDER, B. and CURRERI, A. *Rent control: federal, state, municipal*. (New York: Central Book Co. 1948. Pp. 936. \$15.)
- GLASS, R. *The social background of a plan—a study of Middlesbrough*. (London: Rutledge & Kegan Paul. 1948. Pp. xiv, 268. 42s.)
- GREENE, L. S. and others. *Rescued earth; a study of the public administration of natural resources in Tennessee*. (Knoxville: Univ. of Tennessee Bur. of Public Admin. 1948. Pp. 204.)

NOTES

NOMINATION OF OFFICERS

The nomination of officers of the AMERICAN ECONOMIC ASSOCIATION for the year 1950 having been completed by the electoral body, the Executive Committee decided that the names of nominees should be made public at once, instead of being kept secret until the ballots were distributed, as heretofore.

The nominations were as follows:

For President: Frank H. Knight

For Vice Presidents: Edward S. Mason, Clair Wilcox, Edwin E. Witte, Arynness Joy Wickens.

For Executive Committee: Vincent W. Bladen, Lester V. Chandler, Robert A. Gordon, William J. Nicholls.

Two vice presidents and two members of the Executive Committee will be chosen by ballot.

OFFICERS OF ALLIED SOCIAL SCIENCE ASSOCIATIONS

The Allied Social Science Associations are being served by the following officers during the present year:

American Accounting Association: R. L. Dixon, University of Michigan, Ann Arbor, Michigan, president; Clete Chizek, University of Chicago, Chicago 37, Illinois, secretary-treasurer.

American Association of University Teachers in Insurance: J. Anderson Fitzgerald, College of Business Administration, University of Texas, Austin, Texas, president; J. Edward Hedges, School of Business, Indiana University, Bloomington, Indiana, secretary-treasurer.

American Farm Economic Association: Oris V. Wells, Bureau of Agricultural Economics, Washington 25, D.C., president; L. H. Simerl, 305 Mumford Hall, University of Illinois, Urbana, Illinois, secretary-treasurer.

American Finance Association: Neil H. Jacoby, University of California, Los Angeles, California, president; Edward E. Edwards, Indiana University, School of Business, Bloomington, Indiana, secretary-treasurer.

American Marketing Association: Harvey W. Huegy, University of Illinois, Urbana, Illinois, president; George H. Brown, University of Chicago, Chicago 37, Illinois, secretary.

American Sociological Society: Talcott Parsons, Harvard University, Cambridge, Massachusetts, president; Irene B. Taeuber, University of Maryland, College Park, Maryland, secretary-treasurer.

American Statistical Association: Simon Kuznets, 7301 Mountain Ave., Melrose Park, Philadelphia, Pennsylvania, president; Merrill M. Flood, 1603 K St., N.W., Washington 6, D.C., secretary-treasurer.

Econometric Society: Ragnar Frisch, University of Norway, Oslo, Norway, president; William B. Simpson, University of Chicago, Chicago 37, Illinois, secretary.

Industrial Relations Research Association: Sumner H. Slichter, 229 Littauer Center, Harvard University, Cambridge 38, Massachusetts, president; William H. McPherson, Institute of Labor and Industrial Relations, University of Illinois, Champaign, Illinois, secretary-treasurer.

Institute of Mathematical Statistics: J. Neyman, University of California, president; Paul S. Dwyer, University of Michigan, Ann Arbor, Michigan, secretary-treasurer.

RESEARCH IN ECONOMIC HISTORY

The Committee on Research in Economic History sponsored by the Social Science Research Council, has found an opportunity for the extension of work in its chosen field of the relation of government to American economic development in the explorations being conducted by Professor Carter Goodrich of Columbia University with collaboration from a group of graduate students at that institution. To assist Professor Goodrich in the stimulation of these studies, the Committee has made a grant to him which will permit him to aid financially the young men who are making their investigations under his general direction. The graduate students whom he has selected for inclusion within his group are Carter H. Golembe, Benjamin J. Klebaner, Nathan Miller, and Harvey H. Segal. These men will be designated Resident Fellows in American Economic History at Columbia. Mr. H. Jerome Cranmer of this same group has been given a grant-in-aid.

The Committee has also expressed approval of the efforts being made in an exploration of the area of entrepreneurial history, which has been going forward in 1948-49 at Harvard. To aid this Research Center in Entrepreneurial History, it has voted financial aid for 1949-50 to four young men associated with it: Hugh G. J. Aitken, David S. Landes, Harold C. Passer, and R. Richard Wohl. These men have also been designated Resident Fellows in Economic History.

The Committee has concluded its examination of applications for its National Fellowships in Economic History for the year 1949-50. The following men have been selected: Whitney K. Bates of the University of Wisconsin, Ping-ti Ho of the University of British Columbia (a candidate for the doctor's degree at Columbia University), Douglass C. North of the University of California at Berkeley, Jelle C. Riemersma of the same institution (reappointed now for a second year), Arthur J. R. Smith of Harvard, and Lloyd Ulman of the same institution.

Other grants have been made to Mr. Robert B. Johnson of Virginia Union University, Professors M. A. Adelman and Robert K. Lamb of the Massachusetts Institute of Technology, and Mr. John T. O'Neil of the University of North Carolina.

The chairman of the Committee is Professor Arthur H. Cole, Box 37, Cambridge 38, Massachusetts.

NEW PUBLICATIONS

A series of Bulletins on Soviet Economic Development, edited by Professor Alexander Baykov, is to be published by the Department of Economics and Institutions of the U.S.S.R., University of Birmingham, England. The first series will consist of four Bulletins, to be published during 1949, devoted to the development respectively of: industry, agriculture, finance, internal trade and foreign trade. The Bulletins will be available only to those who subscribe for a series. Subscription for the first series of four Bulletins: £1 0 0 (post-free to any part of the world). Payments should be written to the Department as named above.

A quarterly bulletin, *Current Economic Comment*, which should be of interest to many members of the Association, is being issued by the Bureau of Economic and Business Research at the University of Illinois.

Necrology

Frank A. Fetter, March 21, 1949. A memoir will be published in the September number of this *Review*.

Paul Haensel, February 28, 1949.

Albert H. Mowbray, January 7, 1949.

Kenneth T. Setre, January 23, 1949.

Edward Carroll Sibley, January 6, 1949.

Appointments and Resignations

Clark L. Allen has resigned as associate professor of economics at Duke University to become chairman of the department of economics of Florida State University.

V. Lewis Bassie has been appointed professor of economics and director of the Bureau of Economic and Business Research at the University of Illinois.

A. V. Berger-Voesendorf, formerly of Farouk University, Alexandria, Egypt, is now at Gonzaga University.

Max Bloch has taken a position in the Social Security department of the United Automobile Workers, CIO.

Ed. J. Böling is instructor in statistics, College of Business Administration, University of Tennessee.

Kenneth E. Boulding has been appointed professor of economics at the University of Michigan, effective in the fall term.

Mary Jean Bowman was lecturer in economics during the spring semester at the University of California, Berkeley.

Dorothy S. Brady was appointed professor of economics at the University of Illinois in September, 1948.

Leslie J. Buchan, of Tulane University, has been appointed dean of the School of Business and Public Administration, Washington University.

J. M. Buchanan is associate professor of economics in the College of Business Administration, University of Tennessee.

Reynold Carlson, of Vanderbilt University, will be with the United Nations staff, Santiago, Chile, this summer, as economic consultant.

Paul S. Carter is instructor in accounting in the College of Business Administration, University of Tennessee.

Clyde J. Crobaugh, formerly of Fenn College, is professor of finance in the College of Business Administration, University of Tennessee.

Howard A. Cutler is instructor in economics at the University of Illinois.

Anthony Dawson was acting lecturer in economics at the University of Washington in the spring quarter.

John F. Due has been appointed associate professor of economics at the University of Illinois.

George Filipetti, of the University of Minnesota, has been appointed by the National Management Council of the United States delegate in education to the ninth International Management Congress to be held in Brussels.

Richard W. Fisher has joined the staff of the University of Kansas as instructor in accounting.

James B. Foxworth will join the staff of the department of economics and commerce of the University of Chattanooga as instructor this summer.

Donald A. Gardiner, formerly of the University of Buffalo, is assistant professor of statistics, College of Business Administration, University of Tennessee.

Gilbert L. Gifford, formerly of the University of Washington, is associate professor of transportation, College of Business Administration, University of Tennessee.

Marion H. Gillim, on leave of absence from Mount Holyoke College, is with the Office on Foreign Labor Conditions of the Department of Labor.

Eli Ginzberg, on leave of absence from Columbia University, is serving as director of the New York State Hospital Study.

Everett E. Hagen is professor of economics at the University of Illinois.

James K. Hall, of the University of Washington, has been granted sabbatical leave for the academic year 1949-50 to engage in economic research.

Jean C. Halterman has been appointed instructor in business organization and management in the College of Business Administration, University of Nebraska.

Clifford M. Hardin, professor of economics at Michigan State College, has been appointed director of the college's agricultural experiment station.

Einar Hardin has joined the faculty of the University of Minnesota as instructor in economics.

Victor C. Heck, of Vanderbilt University, has accepted an appointment as professor of economics and chairman of the department of economics and business administration, Mercer University.

Vern G. Hefte, formerly of the University of Iowa, is assistant professor of accounting in the College of Business Administration, University of Tennessee.

Oris C. Herfindahl was appointed instructor in economics at the University of Illinois in September, 1948.

Hans Heymann is lecturer in economics at the University of Illinois.

Abraham Hirsch, formerly of the National Bureau of Economic Research, is now assistant professor of economics at the College of William and Mary.

Malcolm W. Hogg was appointed assistant professor of economics at the University of Illinois in September, 1948.

Harriet D. Hudson was appointed assistant professor of economics at the University of Illinois in September, 1948.

Leonid Hurwicz has returned to his position at Iowa State College after a year's service with the Economic Commission for Europe of the United Nations.

A. L. V. Ingram has been appointed assistant professor of economics at Wofford College, South Carolina.

Allen H. Keally, formerly of the University of Pennsylvania, is associate professor of industrial management, College of Business Administration, University of Tennessee.

Charles C. Killingsworth has been promoted to professor and head of the department of economics at Michigan State College.

E. A. Kincaid has resigned as economist and vice president of the Federal Reserve Bank of Richmond and will devote full time to his work as professor of economics at the University of Virginia.

Carl Kreider, of Goshen College, has been appointed director of the Workshop in Higher Education to be held at the University of Minnesota this summer.

Clarence E. Kuhlman, formerly of the University of Mississippi, is associate professor of transportation, College of Business Administration, University of Tennessee.

Dorothy Lampen has been promoted to the rank of associate professor of economics at Hunter College.

John Lindberg, formerly of the Institute for Advanced Studies at Princeton, served as visiting associate professor of economics at Swarthmore College during the academic year 1948-49.

John Lobb has been named chairman of the department of economics and sociology of Mount Holyoke College.

Donald Love has been appointed part-time instructor in economics at Lafayette College.

Arthur W. Marget is director of the Finance Division, Office of the Special Representative, Economic Cooperation Administration, in Paris. He was incorrectly reported special financial adviser, U. S. Embassy, Paris in the December number of this journal.

Raymond H. McEvoy was appointed assistant professor of economics at the University of Illinois in September, 1948.

Leon Megginson has been appointed instructor in management, Louisiana State University.

Charlotte F. Muller was lecturer in economics in the spring semester at the University of California, Berkeley.

Edward G. Nelson has been promoted from associate professor to professor of economics at the University of Kansas.

William H. Nicholls, of Vanderbilt University, will teach during the summer session at the Salzburg, Austria, Seminar in American Studies, sponsored by the Harvard Student Council and the World Student Service Fund.

Ralph P. Norton has resigned as instructor in labor and industrial relations, University of Illinois, to edit the Vermillion County Star newspaper in Danville, Illinois.

Louis W. Nuesse is associate professor of industrial management in the College of Business Administration, University of Tennessee.

John E. Orchard, of the School of Business, Columbia University, has joined the staff of the Economic Cooperation Administration, Paris.

Morton Paglin has been appointed instructor in economics in the College of Commerce, Louisiana State University.

Don Patinkin, formerly associate professor of economics at the University of Illinois, is now lecturer in economics at the Hebrew University in Jerusalem.

Gardner Patterson has been appointed to the directorship of the International Finance Section of the department of economics and social institutions at Princeton University.

Frank C. Pierson is on leave of absence from Swarthmore College to direct research in labor economics at the University of California at Los Angeles.

Charles L. Quittmeyer has resigned from the Connecticut General Life Insurance Co. to become assistant professor of economics and business administration, College of William and Mary.

E. G. Rasmussen, who has been on a General Education Board fellowship at the Harvard School of Business Administration, will resume his work at Vanderbilt University beginning with the summer quarter.

Margaret G. Reid was appointed professor of economics at the University of Illinois in September, 1948.

Ronald Reifler has been appointed instructor in the economics department of Claremont Men's College.

Raymond J. Saulnier has been promoted to the rank of professor of economics at Barnard College.

Willard J. Saunders has been appointed assistant professor of business administration at San Jose State College.

Wilson E. Schmidt has been appointed instructor in economics at the University of Virginia.

Ned H. Scott has been appointed instructor in accounting at the University of Florida.

Edith G. Severo will act as substitute for Mrs. Janet Sundelson, who has been granted leave of absence from Barnard College for the academic year 1949-50.

Everett R. Shaw is assistant professor of economics at Arizona State College.

Joseph Shister, of Yale University, has been appointed associate professor of industrial relations in the school of Business Administration, University of Buffalo.

Carl S. Shoup, of the School of Business, Columbia University, is directing a study of the Japanese tax system for the United States Army in Japan.

Lewis B. Sims, who was detailed to the Hoover Commission from his position as assistant chief of the Governments Division of the Census Bureau, has now transferred to the Public Health Service.

Edward L. Smith has been promoted to the rank of associate professor of economics at Hunter College.

Douglas B. Smith was appointed instructor in economics at the University of Illinois in September, 1948.

Dallas W. Smythe was appointed professor of economics in the Institute of Communications Research, University of Illinois, in September, 1948.

Thorn K. Snyder has been appointed instructor in economics at Purdue University.

Frank A. Southard, Jr., has resigned as associate director of the Division of Research and Statistics of the Board of Governors of the Federal Reserve System to accept the position of United States executive director of the International Monetary Fund.

Edwin H. Spengler has been promoted from associate professor to professor in economics at Brooklyn College.

David K. Spiegel has been promoted from instructor to assistant professor of economics at Pratt Institute.

Ross Stagnår, formerly of Dartmouth College, has joined the staff of the University of Illinois as professor in labor and industrial relations.

Jack Stieber has resigned as instructor in economics at the University of Minnesota to be assistant director of research for the United Steel Workers' Union in Pittsburgh.

Robert M. Strahl, formerly of the University of Nebraska, is associate professor of marketing, College of Business Administration, University of Tennessee.

Theodore A. Sumberg has accepted an appointment as economist for the new fortnightly magazine, *The Reporter*.

Boris C. Swerling has been promoted to assistant professor of economics at Brown University.

A. G. Taylor, head of the department of political economy, has been elected Chancellor Distinguished Professor by the Board of Visitors of the College of William and Mary.

W. Bayard Taylor, of the University of Wisconsin, has joined the staff of Claremont Men's College as professor of business economics.

C. F. Joseph Tom was appointed instructor in economics at Beloit College in September, 1948.

E. T. Towne retired as dean of the School of Commerce, University of North Dakota, in September, 1948.

Joseph F. Trosper, formerly of Indiana University, is instructor in economics in the College of Business Administration, University of Tennessee.

Charles J. Walsh is serving as consulting economist to the Research Institute of America in addition to teaching in the Graduate School of Fordham University.

Ralph J. Watkins, of the School of Business, Columbia University, is serving as director of the Office of Plans and Programs, National Security Resources Board.

E. T. Weiler was appointed professor of economics at the University of Illinois in September, 1948.

Morris Weisz, formerly with the National Labor Relations Board, is temporarily special assistant to the Commissioner of Labor Statistics, Department of Labor.

Edmund Whittaker, formerly of Indiana University, has joined the faculty of Colorado Agricultural and Mechanical College.

Jack H. Wilcox, formerly of Missouri Valley College, is associate professor of finance, College of Business Administration, University of Tennessee.

Charles W. Williams has resigned as professor of economics at the University of Louisville, Kentucky, to become vice president of the Federal Reserve Bank of Richmond.

H. Lawrence Wilsey has been appointed assistant dean of the College of Commerce and Business Administration, University of Southern California.

Herman J. Wyngarden, professor of economics at Michigan State College, has been appointed dean of the college's School of Business and Public Service.

Theodore O. Yntema has resigned as research director of the Committee for Economic Development. He is now vice president of the Ford Motor Company for Finance.

ALLYN ABBOTT YOUNG

*Twenty-seventh President of the
American Economic Association, 1925*

Allyn A. Young was born at Kenton, Ohio, September 19, 1876. He died in London, March 6, 1929.

Allyn Young's academic career was remarkably varied. After receiving his Ph.B. degree from Hiram College, Ohio, in 1894 and his Ph.D. from Wisconsin in 1902, he moved consecutively from Western Reserve University, to Dartmouth College, to Leland Stanford (where he was head of the department of economics, 1906-11), to Washington University at St. Louis (professor of economics, 1911-13), to Cornell (professor of economics and finance, 1913-20), thence to Harvard (professor of economics, 1920-), and finally to the University of London (professor of political economy from 1927 until his death in 1929).

While eminently competent as a scholar and teacher in a wide range of economics, he left behind him no large body of publications. He wrote a great many reviews and notes and some elaborate papers, the more notable of which were assembled in a volume entitled, *Economic Problems New and Old*, published in 1927. *An Analysis of Banking Statistics* (1927) was reprinted from the *Review of Economic Statistics*. He was joint author of the 1909, 1916, and 1923 revised editions of Richard T. Ely's *Outlines of Economics*.

After the war he served as a member of the Massachusetts Commission on Pensions. He also assisted Jeremiah Smith in the rehabilitation of Hungary under the auspices of the League of Nations.

A minute, prepared by a committee of the American Economic Association, was published in the June, 1929, issue of the *American Economic Review*, pages 346-348.

NEOCLASSICAL ECONOMICS AND MONETARY PROBLEMS

By PAUL B. SIMPSON*

In his *Price Flexibility and Employment*, Professor Oscar Lange maintains that neoclassical thought is incapable of dealing with problems of money, trade fluctuations, and unemployment because it utilizes a method of partial equilibrium to analyze problems of total effects, and for such problems only a method of general equilibrium is applicable.¹ This paper considers the relation of classical or traditional thought to monetary and employment theories and illustrates the points with brief discussion of the works of some outstanding orthodox economists. The point of view presented is that neoclassical thought in its conception embraces monetary subjects but through an unfortunate association with static systems has become divorced from these important subjects. With this background, Lange's argument will be examined.

I

Neoclassical economics is a body of analysis derived from postulates concerning individual behavior in its efforts to maximize well-being. Individualistic and hedonistic in its approach, as formulated by Adam Smith, it has not been changed in this respect. Keynesian and other systems of thought also appeal to these principles, though scarcely as directly and completely as classical thought. About this there is little disagreement. The question of the relation of traditional thought to monetary economics turns on the interpretation and generality of those individualistic hedonistic behavior principles. If they are con-

* The author is associate professor of economics at the University of Oregon.

¹ *Price Flexibility and Employment* (New York, 1944), p. 1. Professor Lange uses the terms traditional and orthodox economics without specifying the economists so described. Reading of the text indicates that Lange has reference to the English neoclassical and the Lausanne schools primarily.

fined to individual choice under known conditions, that is under conditions of certainty, then the maximizing behavior is of a very constrained sort. If such be the nature of traditional thought, then it must be granted that problems of monetary behavior, trade fluctuations, and the like are outside the area of such thought. For individual choice under certainty is the basis of an economic system of equilibrium where money and trade fluctuations are of little or no importance. If, on the other hand, traditional thought covers the case of individual efforts to maximize welfare under conditions of uncertainty, then there is every reason why it should be germane to the broad problems of monetary economics.

The correspondence of economic systems postulating choice under certainty with equilibrium systems is well understood.² If each individual knows his alternatives, then each individual succeeds in maximizing his welfare. No improvement is possible from an individualistic point of view, no individual can be under motivation to regret or alter his decision. Equilibrium exists. If, on the other hand, individuals must decide their actions under uncertainty, then some regrets and changes of plans are sure to occur. Disequilibrium exists, and the time sequence of events will show fluctuations inconsistent with an optimum allocation of resources.³

The importance of certainty postulates in the creation of economic systems and the great effect that they have on the nature of a body of thought can be illustrated with a simple example. Assume (1) there is one good a , produced by one factor, labor, l ; (2) one unit of

² Professor Frank Knight first made this equivalence clear. *Risk Uncertainty and Profit* (Boston, 1921).

³ Professor Paul A. Samuelson and Professor Ragnar Frisch distinguish statics from dynamics on the basis of the importance of time in determining the evolution of the analytical system. Professor Erik Lindahl and Professor J. R. Hicks have adopted quite similar definitions. It is not hard to see that uncertainty is the basic element giving rise to the essentiality of time in the economic process, since under uncertainty the basic determinants are modified or overpowered by the events of time. The very essence of behavior under uncertainty is that judgments are revised as experience is gained.

It seems to the writer preferable to emphasize the postulutory basis rather than a property of analysis in distinguishing statics and dynamics. There is danger of defining a system that has little meaning economically when analytical properties are put in the foreground. Thus the Samuelson system of stability in multiple markets,

$$dp_i/dt = F_i(p_1, p_2, \dots, p_n) \quad i = 1, 2, \dots, n$$

where p_i is the deviation from equilibrium price, has only a very loose economic interpretation since it does not specify what transactions take place. Professor Lange very likely has tripped over the interpretation of this system, which he develops in the appendix of the work cited. Paul A. Samuelson, *Foundations of Economic Analysis* (Harvard University Press, 1947), pp. 311-17. Ragnar Frisch, "On the Notion of Equilibrium and Disequilibrium," *Rev. Econ. Stud.*, Vol. III (Feb., 1936), p. 100. Erik Lindahl, *Studies in the Theory of Money and Capital* (New York, 1939), pp. 31-40. J. R. Hicks, *Value and Capital* (Oxford, 1939), p. 115.

labor makes one unit of a ; (3) the price of labor is $100 = p_1$; (4) each laborer acts as his own entrepreneur; (5) savings are zero; (6) labor supply is a function of real income, say $f(a)$; (7) each laborer knows that he can work for the price 100 and that the price of a will be 100. Under such assumptions equilibrium conditions are that the price of labor be 100 and that the supply equal demand of labor, and there is no doubt that equilibrium will be achieved.

If we suppress assumption (7) dealing with foresight, we must replace it with a new specification of behavior under conditions of uncertainty. Out of the infinite possibilities for the form of such postulates we can select in place of (3) and (7) above the following: (3') the price of labor lowers in a time period by a proportion of the unemployment of the previous period; (7') production in time t changes by a constant per cent of the indicated profit in time t : (7'') the price of labor in time t is known and the price of a in time $t-1$ is expected to remain unchanged throughout t . It follows that if employment is below the equilibrium level, the price of labor falls, the anticipated profits increase, employment increases, and the economy moves toward equilibrium, though it would not reach it in finite time. A possible sequence of events starting from a particular point and using particular constants is shown in the following table.⁴

t	p_1	a
0	100.0	90.0
1	99.0	92.0
2	98.2	93.6
3	97.6	94.9
4	97.0	95.9
∞	95.0	100.0

⁴ Mathematically we have the system

$$\begin{aligned} p_{1t} &= p_{1t-1} - k_1 (L - a_{t-1}) \\ a_t &= a_{t-1} + k_2 (p_{at-1} - p_{1t}) \end{aligned}$$

where L , k_1 , k_2 are positive constants. But since savings are zero, the value of production equals the value of income disbursements and the price of labor and of a are equal, i.e. $p_{at} = p_{1t}$. Substituting and solving, one obtains

$$\begin{aligned} p_{1t} &= (L - a_0) (1 - k_1 k_2)^t / k_2 + p_0 + (a_0 - L) / k_2 \\ a_t &= L + (a_0 - L) (1 - k_1 k_2)^t \end{aligned}$$

which yield stable solutions if $k_1 k_2 < 1$. The solution which yields the table above was obtained by using $k_1 = .1$ and $k_2 = 2$.

It will be observed that this system postulates behavior without a very thorough theory of maximization of welfare. Nor are the monetary properties described. To fill these deficiencies would require more space than would be justified, although a truly classical dynamic system demands that it be done.

By stating the behavior postulates in precise form under conditions of uncertainty, an evolutionary or dynamic picture is achieved which passes beyond equilibrium states and which is much more general in its conception. By complicating the behavioristic assumptions under uncertainty, and also by complicating the structural elements, *i.e.*, the number of commodities, properties of production functions, etc., diverse analytical models can be created.

The key to appraising the relation of traditional thought to monetary economics lies in its position relative to uncertainty. Other issues such as that of general *versus* partial equilibrium are of secondary importance. In so far as traditional thought confines itself to conditions of certainty, it fails to be a monetary system. In so far as it involves behavior under more general circumstances, it is potentially at least a monetary system. It is from this standpoint that it is proposed to consider some instances of economic analysis.

Since traditional thought is so widely represented in economic literature, it is not possible to characterize its treatment in a simple formula. A surprisingly large amount of traditional thought, however, can be represented under three headings, as follows: (1) Classical works proper in which both certainty and uncertainty economics are represented, but in which the relation of the two is never clearly expressed, Adam Smith, T. R. Malthus and Alfred Marshall being outstanding examples; (2) Classical writers who exclude uncertainty elements almost entirely⁵—exemplified by David Ricardo, J. B. Clark, Lionel Robbins,⁶ and Frank Knight; (3) Classical writers who attempt to construct uncertainty or dynamic systems on the basis of certainty or static systems—examples, A. C. Pigou, Knut Wicksell, Friederich von Hayek, D. H. Robertson, and J. R. Hicks. We shall discuss briefly one writer from each of these groups, namely, Marshall, Knight, and Hicks.

II

Marshall's *Principles of Economics* makes every effort to be a monetary economics and economics of uncertainty, though it does not

⁵ Don Patinkin has taken this attitude toward classical economics in his interesting essays on the subject. "Relative Prices, Say's Law, and the Demand for Money," *Econometrica*, Vol. 16, No. 2 (Apr., 1948), p. 127; "The Indeterminacy of Absolute Prices in Classical Economic Theory," *Econometrica*, Vol. 17, No. 1 (Jan., 1949), p. 1.

Professor Joseph Schumpeter could be included in this list, since Schumpeter uses classical thought to define Normality and as "*a description of an apparatus of response*" (Schumpeter's italics). This dualism raises a good many theoretical issues which cannot be gone into here. *Business Cycles* (New York, 1939), p. 68.

⁶ The characterization of economics as the study of allocation of scarce resources among given ends implies static or certainty postulates or else is very vague. Lionel Robbins, *An Essay on the Nature and Significance of Economic Science* (London, 1932), pp. 12-15.

achieve such a goal. Certainty or static formulations are avoided; behavioristic postulates are stated. If the result is not a monetary or dynamic system, the reason is that the problem is too large, not that the attempt is not made. Let us note first the behavioristic assumptions which Marshall uses. A tolerably complete listing of such assumptions, omitting the broader and more institutional assumptions, is shown below:

1. With a given income and with a given price situation a consumer spends his income so as to maximize his utility. Marginal utility of a good decreases with the amount purchased, other quantities constant. Anticipated future utilities are discounted at a known rate by each consumer, and allocation made for future consumption in the light of alternatives determined by interest rates and anticipated future prices. (Book III, Chaps. IV and V.)
2. The amount of saving by a consumer is determined mainly by personal and social factors but in general increases with interest rates. (Book IV, Chap. VII.)
3. The amount of work which an individual worker will do is an increasing function of the price of work. (Book IV, Chap. I.)
4. A farmer allocates his expenditure upon land, capital, and labor so as to maximize his estimated returns from his total expenditure. (Book IV, Chap. III.)
5. The numbers of youths educated in particular skills are increasing functions with distributed time lags of the wages in those skills. The numbers of workers of a particular skill employed in particular firms and industries are similarly functions of wages in the firms and industries. (Book IV, Chap. VI.)
6. The supply of business management is a function of the price of management and of the individual managers' abilities to command confidence in borrowing money. (Book IV, Chap. XII.)
7. For the anticipated prices of sales of a product at a given time in the future, and the anticipated costs of variable factors relevant to that time, each businessman acts to minimize his costs of production and to maximize his expected profit. (For capital goods the cost is interest.) (Book V, Chap. V.)
8. Businessmen's calculations are disturbed by uncertainty. (Book V, Chap. VII.)

Is this set of behavior postulates when fitted out with proper definitional, descriptive, and identity relations an adequate foundation for the erection of an economic system or not? The answer must be no. If one suppresses the uncertainty elements in postulates 5, 6, 7, and replaces them with a postulate that foresight is perfect, one does have a sufficient set of postulates for an equilibrium economy. This, Marshall does not intend. He rebels at the notion of stationary states and static equilibrium, and he frowns on mathematical methods which express such conditions. His emphasis is on the continuity of change; the gap between the time of economic planning and the occurrence of events derived from those plans is never forgotten. Moreover, when Marshall is on guard he himself sees that the evolution of events is

not explicable in terms of equilibrium determinants, and that the source of the difficulty is uncertainty. This is evident in the inclusion of uncertainty among the postulates of behavior listed above, and in many passages, for example the following: "We cannot see the future perfectly—the unexpected may happen and the existing tendencies may be modified before they have had time to accomplish what appears now to be their full and complete work" (p. 347).

If we deny that the Marshallian system is an equilibrium system (which we clearly must), and interpret it as a dynamic or uncertainty system, we find it an inadequate work. The only solution to the dynamic problem which Marshall found was to use equilibrium determinants as the motivators of change, as kind of will-o'-the-wisps beckoning the real economy, but always evading grasp. "The demand and supply schedules do not in practice remain unchanged for a long time together—this gives new positions to the center about which the amount and the price tend to oscillate" (p. 364). Equilibrium evidently affects the dynamic process, but just how is not clear. There is no definitive economics of change.

The source (and reflection) of the difficulty is evident in the postulates which have been listed above. The postulates are not adequate for the creation of a disequilibrium system. Postulates 6 and 7, particularly, are vague. An entrepreneur makes plans on the basis of expected prices. But by what process does he determine expected prices? Does he use present prices, past prices, extrapolated trend prices or what? And having determined his expectations, how definitively does he act on those expectations? One possibility particularly was neglected, namely, that an entrepreneur will do nothing temporarily except to wait for more evidence to accumulate about the factors that influence his well-being. How the economic system operates depends on the specific assumptions made.

Postulates 7 and 8 above are not only vague but are formulated so as to be inadequate for the creation of uncertainty systems. Suppose that it is assumed that entrepreneurs follow a particular system of forming expectations about future prices, for example that they expect present prices to persist. If they form these expectations precisely and with conviction, they will be able to calculate the profit realizable from each possible economic activity. They would seize then upon the most profitable and act upon it with thoroughness. They would go completely into or completely out of cash. Economic movements would be violent, especially if different entrepreneurs had similar anticipations. In fact, reactions would be so violent that entrepreneurs would soon cease to hold their anticipations with such certainty. Such precision of expectations does not yield a sensible economic system. Expectations must be in terms of probabilities if there is to be a sensible

hedonistic economics of uncertainty, particularly if money is to be introduced into the system. Marshall's postulates not only do not define behavior precisely, but are formulated in terms that cannot be used satisfactorily for a precise statement.

It is not easy to recognize this lack of precision in Marshall's work, because he has treated the matter of expectations in a general sense with thoroughness. The types of information which may affect expectations and plans are nowhere better described. For example, we are introduced to the speculative builder who weighs every type of evidence regarding the costs and demands for homes before building. The workings of the minds of the grain merchant and the clothmaker are even more fully explored. The consideration of a particular set of possible modes of decision-making is lacking, and this lack is critical.

Since the postulates themselves are inadequate for construction of an uncertainty system, the deductive consequences of any assumed formulation of economic behavior under uncertainty cannot be effectively stated. Even if we read Marshall's description of individual behavior as a theory of speculation, it is not clear what the consequences are. Marshall resorted to approximations to equilibrium, and this is obviously not adequate as a description of the economic process. Speculative behavior does not necessarily lead to equilibrium; we need to know when, how, and in what degree it does lead to equilibrium.

The point to be emphasized is that the problems of creating an uncertainty economics are well presented in Marshall. These are: (1) how to state principles of behavior when individuals attempt to maximize welfare under conditions of uncertainty, (2) how to combine these principles with assumed sets of economic experience of individuals to obtain the implied actions of individuals, (3) how to trace the economic consequences of (1) and (2) in the whole economic system, thus determining the experience of individuals (and hence the data of (2) at a later date). Later writers have tended to seize upon the defects of Marshall's equilibrium system for comment and correction, and have neglected the important questions posed by the work.

In recent times much has, however, been done in developing the uncertainty elements of Marshall's work, though with little stress upon the relation of this work to the Marshallian tradition. For example, the translation of maximization of welfare principles into uncertainty situations through the use of probability notions has been made by various writers. More formalistic statements have been suggested by Professor Gerhard Tinter and Professor J. Marschak.⁷ These

⁷ Gerhard Tinter, "The Theory of Choice Under Subjective Risk and Uncertainty," *Econometrica*, Vol. 19, Nos. 3 and 4 (July and Oct., 1941), p. 298, and "A Contribution to the Nonstatic Theory of Production," *Studies in Mathematical Economics and Econometrics*

statements are simple extensions of classical statements and are adequate to show, for example, that speculative monetary behavior is an inherent part of rational behavior. If price estimates are probability estimates, then the holding of money has certain advantages readily stated in terms of traditional maximization theory.

Investigations have been made into the implications of economic behavior under uncertainty. For example, Professor Frisch's work on production time lags deals with the effects of investment decision on future economic life and thus deals with the implications of decisions made on the basis of past experience and uncertain knowledge of the future.⁸ This study is directly related to the Marshallian notions of long- and short-run costs. The cobweb theorem, the accelerator principle, and studies of inventory cycles also consider the implications of patterns of decision-making under uncertainty.

Many empirical studies develop and consider dynamic patterns of behavior. Reference is to such studies as those of the National Bureau of Economic Research on cash balances, inventories and professional income, and to such as those of Professor J. Tinbergen on factors affecting entrepreneurial decisions of investment. It seems likely that the development of theoretical uncertainty systems will require such empirical grounding, since the number and complexities of plausible *a priori* systems are greater than for equilibrium economics. It is surely possible and perhaps desirable that these researches be better coordinated with a general dynamic or uncertainty system of thought built up along Marshallian lines.

III

Professor Frank Knight was foremost among those who saw the difficulty in Marshall discussed above, namely the looseness of the relation between behavior under uncertainty and equilibrium analysis. *Risk, Uncertainty, and Profit* is largely devoted to the task of making classical thought rigorous.⁹ This objective is tackled and achieved in the sense that definitions and assumptions are made precise under the special conditions of certainty. The result is an excellent criticism of

(University of Chicago Press, 1942); J. Marschak, "Money and the Theory of Assets," *Econometrica*, Vol. 6, No. 4 (Oct., 1938), p. 311.

⁸ Ragnar Frisch, "Propagation Problems and Impulse Problems in Dynamic Economics," *Economic Essays in Honour of Gustav Cassel* (London, 1933), pp. 171-205.

⁹ "We have developed an historic body of theoretical economics which deals with 'tendencies,' i.e., with what would happen under simplified conditions never realized, but always more or less closely approached in practice. But theoretical economics has been much less successful than theoretical physics in making the procedure useful, largely because it has failed to make its nature and limitations explicit and clear." *Op. cit.*, p. 16.

classical thought and the beginning of a new type of institutional economics. From the standpoint of technical economic analysis, the work, however, had the unfortunate tendency of constraining classical thought to ideal and unreal situations.

An outline of the work is sufficient to indicate its nature. We have first a picture of economic life under conditions of certainty, that is, an equilibrium system or, as Knight calls it, a system of perfect competition. We are introduced to the calculations of a boy eating berries, the weighing of costs and returns of the healthy appetite which knows what it wants and how to get it. We follow to the more complicated calculations of Robinson Crusoe, to the pure exchange economy, and finally to the specialized capitalistic economy. We are shown in brilliant exposition that as long as the alternatives open to each individual can be clearly formulated, an economic system based on such foundations makes sense and possesses certain optimum properties for human welfare, however complicated and specialized the rôles of the individual members of that economy may be.

The second part of the work is devoted to a consideration of the effects on such a system of uncertainty. If the calculations of individuals are upset by uncertainty regarding their alternatives, what then? We learn that various changes occur in the structure of organized society. Specialists assume the role of estimating alternatives. The entrepreneur and his staff of hired sharers of the task, come into being. And with the new rôle comes a new economic return, profit (and loss), the reward to "superior" ability in appraising the alternatives of economic choice and activity. The place of economic institutions, the firm, management, capitalists, speculators, etc., in the economic task of allocation of economic resources is brilliantly illuminated.

It will be observed that Knight has reversed the Marshallian order of study. Whereas Marshall conceived of behavior first and attempted to deduce the laws of economic life, equilibrium occupying a kind of catalyzing rôle, Knight reverses the approach. He defines equilibrium first, and considers behavior in terms of its relation to equilibrium. This is an excellent device for the purpose of relating the work of economic institutions to the aim of economic life. The contrast of the straight road of economic life with the crooked road can be used to explain the nature of things. It is not, however, a good device for improving the understanding of the economic process itself as distinct from the kind of forces which act on it. The Marshallian task of describing the dynamic process is circumvented. By taking equilibrium as his point of departure, Knight constrains classical thought. Monetary and dynamic problems are excluded. The approach is essentially moralistic and philosophical.

IV

Professor J. R. Hicks in *Value and Capital* has undertaken an extension of equilibrium economics to a monetary system. He uses equilibrium conditions as a basis for a set of dynamic determinants, reinterpreting the formal relationships of equilibrium in a wider significance. He believes that the method of general equilibrium makes possible this expanded use of equilibrium notions.¹⁰ Unfortunately, however, Hicks neglects the behavioristic part of his apparatus. By overlooking the implicit behavioristic assumptions of static analysis, he puts more weight on the formal determinants than they can bear, and the attempt to build a dynamics out of statics fails. There is triumph in this failure, however, since it is done so explicitly that it exposes the impossibility of this approach which has been utilized by many writers, and with ill success.¹¹

Although Hicks develops two analytical schemes, a statics and a dynamics, and characterizes the two on the basis of the exclusion or inclusion of time as a basic ingredient of the system, it is uncertainty that more strikingly distinguishes the two. In the statics there is no mention of choice under uncertainty, all individual choices being made among known alternatives. In the dynamics, uncertainty plays a prominent rôle, the theory of interest in particular being based largely on risk concepts.¹² But the difficulties of uncertainty which are seemingly avoided in the statics actually arise there too. Uncertainty is so treacherous a matter that it rears its ugly head in unforeseen places, and it had caused Hicks trouble before he was aware of its existence.

For purposes of the present discussion it will suffice to consider one phase of Hicks' work, the static pure exchange economy. Hicks uses this model himself and it simplifies the discussion. Production under conditions of certainty is not a source of important complications, and can be safely subordinated. We picture, then, an economy composed of a group of consumers each of whom has an initial stock of one or more of n consumer goods. Trade takes place among the consumers under conditions of perfect competition. What are the terms of trade?

¹⁰ "I believe I have had the fortune to come upon a method of analysis which is applicable to a wide variety of economic problems. . . . The method of General Equilibrium, which these writers (Walras, Pareto, and Wicksell) elaborated, was specially designed to exhibit the economic system as a whole. Our own work is bound to be in their tradition." *Op. cit.*, pp. 1, 2.

¹¹ Paul A. Samuelson has pointed out such difficulties in Hicks' methods. *Op. cit.*, pp. 269-75.

¹² But not exclusively so. A careful reading of Chapters XVII, XVIII, XXIII, and XXIV shows that time preference and productivity of indirect processes are essential parts of the interest determination. Hicks treats these determinants through the device of the effect of interest rate changes on behavior and not conversely, thus very largely concealing their existence.

Hicks defines equilibrium conditions of trade in a thoroughly traditional manner. We have one good chosen for a numéraire and we assume a preference function for each consumer. Equilibrium is determined where (1) the ratio of marginal substitutability of each two goods equals the ratio of prices for each consumer, (2) each individual's budget is in balance, (3) total sales equal total purchases of each commodity. The definition of Walrasian equilibrium by the fulfillment of these simultaneous conditions is conventional and requires no comment here.

Hicks defines stability of equilibrium in terms of excess supply when non-equilibrium prices are considered.¹³ To consider the stability of a market for one commodity a , we consider the price of a to be out of equilibrium, say, for convenience, above the equilibrium level. For the other $n-1$ prices we consider $n-1$ possibilities where any m prices are at new "auxiliary" equilibrium levels preserving equality of demand and supply for them, and the remaining $n-1-m$ prices are at original equilibrium prices. If supply exceeds demand for a in each of these situations, the market is said to be perfectly stable. Thus stability is defined essentially by maintaining conditions (1) and (2) of equilibrium and asking what happens to equation (3) when non-equilibrium prices are considered. The sign of the difference of supply and demand is taken to define stability. Too high a price must create excess supply if the market is to be stable.

With one exception to be noted presently, this is a harmless logical exercise provided it is understood that it is not an economic argument and that nothing is being said about the operations of markets. The problem of how markets behave in disequilibrium cannot be discussed within bounds of assumptions of trade under conditions of certainty. No trade will occur at disequilibrium prices under such conditions. If we maintain conditions (1) and (2) of the equilibrium conditions, condition (3) must be maintained also, since some individual acts contrary to his best interest (assumed in [1]) if supplies and demand are not equal. We thus have a contradiction. To put the argument another way, if trade takes place at non-equilibrium prices, somebody has caused to regret that he allowed these prices to be maintained. Whose those persons are that have such regrets, and what commodities are involved are matters that cannot be discussed within the framework of choice among known alternatives. To discuss disequilibrium market under new assumptions involving speculative and uncertainty behavior are necessary. The old Marshallian dilemma has not been solved.

In one case even the formal properties of the Hicksian stability analysis break down. This is the case of perfect stability. If $n-1$ price

¹³ *Op. cit.*, p. 67 and p. 315.

are at "auxiliary" equilibrium levels, maintaining equality of supply and demand in those markets, the n th price must be an equilibrium price too. There is no meaning to perfect stability as Hicks defines it.¹⁴ If all individual budgets balance at a given set of prices and n - l markets are in equilibrium, the n th market must also be in equilibrium.

The truth is that the Hicksian devices are essentially ones of comparative statics and not of stability. The Slutsky equation interpretation of consumer behavior analyses the change in individual purchases of goods when prices of goods change. But the significance of a price change in a general equilibrium system can only lie in a change of tastes or some other parameter of the system; it has no disequilibrium significance. A price change to a whole system has reflected, but not original, properties. Thus the Slutsky equation and other Hicksian devices for discussing "stability" and "laws of markets" are essentially methods of comparative statics. It is here that the true path of Hicks' analysis lies. The shift in point of view from partial to general equilibrium is important to problems of comparative statics, but it does not meet the problems of uncertainty, dynamics, and monetary events.¹⁵

¹⁴ Hicks' error lies in deriving market supply and demand functions from individual supply and demands derived in turn from equilibrium conditions of individual traders and then considering these aggregate equations independently under nonequilibrium conditions, which he is not entitled to do. The equations still define equilibrium.

We have given consumer preference functions for P people say $\Phi_j(x_i)$, $j = 1, 2, \dots, P$; $i = 1, 2, \dots, n$, and P sets of initial stocks of goods say x_{ij} . Let $p_1, p_2, \dots, p_n$ represent prices which put the corresponding markets in equilibrium. Letting Δ_{ij} denote the quantity which each individual buys (or sells if negative), we have under the hypothesis of perfect stability,

$$\sum_{j=1}^P p_i \Delta_{ij} = 0 \quad i = 2, 3, \dots, n$$

Let p_1 be any price whatsoever for the good 1. Since each individual balances his budget

$$\sum_{j=1}^P \sum_{i=1}^n p_i \Delta_{ij} = 0$$

Aggregating and combining, one obtains

$$\sum_{j=1}^P \sum_{i=1}^n p_i \Delta_{ij} - \sum_{i=2}^n \sum_{j=1}^P p_i \Delta_{ij} = 0$$

or

$$\sum_{j=1}^P p_1 \Delta_{1j} = 0$$

Thus p_1 must be an equilibrium price also. If individual budgets balance there can be no set of prices such that only one of them is out of equilibrium. But perfect stability is defined in terms of one price being out of equilibrium.

¹⁵ Hicks' misunderstanding of the nature of his methods results in another error of importance, namely, the assertion that in a world of substitutary commodities a change in demand will change all prices in the same direction. If trade takes place between A and B, and A has a preference function depending on a parameter a , then a change in a increasing the demand for one good may raise or lower the equilibrium prices of substitutary commodities. Cf. *Value and Capital*, p. 75 and p. 255.

V

Although the extracts from the history of traditional economics are scarcely sufficient to serve as a basis for generalization about the relation of traditional thought to monetary systems, they do suggest certain conclusions. First, is the obvious one that the behavior postulates are fundamental to the statement of economic theories, and that the manner in which the postulates treat the certainty of choice of alternatives is crucial. The temptation to restrict traditional thought to certainty conditions has hindered its development. On the other hand, it was not so restricted in Marshall and there is no reason to restrict it except for the great intellectual labor required for its extension.

Secondly, we note that when traditional thought is viewed in the manner here advanced, much current economic research of a non-static variety does bear on the problem of extending classical thought.

Thirdly, we venture to suggest that monetary systems are essentially short-cut devices to cut through the complexities of erecting a classical system of uncertainty economics out of maximizing postulates. It was perhaps inevitable that pending the establishment of such a basic system, other systems would be forthcoming to fill the intellectual void created by their absence. Reflection upon the nature of the devices utilized in monetary economics indicates that these systems fit that description very well. The basic device is to postulate human behavior in terms very closely allied to the properties of the system which it is desired to determine. In that way the intellectual problem of passing from postulate to conclusion is much reduced, and the economic system made much more manageable.

A familiar example is the quantity theory of money. Here the postulate defines behavior in terms of the ratio of cash balances to expenditures. A whole complex of problems regarding the determinants of expenditures is avoided. Given such a postulate, conclusions regarding velocity, volume of transactions, and price levels are readily forthcoming. A handy tool of analysis is thus provided.

With Keynes, the postulates are more complex although essentially of the sort under discussion. Marginal efficiency of capital, propensity to consume, and liquidity preference are omnibus postulates, determined by all kinds of economic factors. Once given, however, they lead quickly to determinate results. They act as guide posts amongst the complexities of economic life, and are for that reason very convenient and useful.

Lange has now introduced a monetary device of this kind which is of startling simplicity and generality. Human behavior is described in terms of its propensity to accumulate cash, and this propensity is related directly to problems of unemployment of resources. This de-

vice will now be examined to see how adequate it is for the analysis of monetary and employment problems, and to see what light it sheds on the nature of neoclassical economics.

VI

The excess demand for cash balances is a budgetary identity applicable not to what happens in the economic world, but to the plans of all individuals and firms as of a given time. Confronted with a given situation, each individual will have a plan to get into or out of cash at the expense of getting out of or into commodities and securities. The amount of cash which it is planned to accumulate is defined as the excess demand for cash balances. The "accumulation" may be negative in case the desire is to lower cash balances. This aspect of individuals' plans, the contemplated cash accumulations (or releases), is the key to the analysis of the course of economic events so far as employment problems are concerned. All other aspects can be channeled into a consideration of this one.

Consider an individual, firm or household confronted with a set of prices for goods of all kinds, namely, factors, commodities and securities.¹⁶ The individual will decide to buy or sell each good in given amounts during such a time period. Mathematically, if prices are p_i , $i = 1, 2, \dots, n$ and if the quantities he plans to buy or sell are s_i , where a positive s_i denotes a sale and a negative s_i denotes a purchase, his surplus of sales is $x = p_1s_1 + \dots + p_ns_n$. He plans to accumulate a given amount of cash x which is his individual excess demand for cash balances. If his excess demand for cash balances is negative, it means that he finds prevailing prices so attractive that he plans to lower his cash balances over the period.

Since the individual's excess demand for cash balances refers to his plans and not to his actions, there is no difficulty in passing from individual to aggregate excess demand for cash balances of the entire economy. The sum of individual excess demands is the aggregate excess demand for cash balances, which is also the total quantity of money which the whole community would like to accumulate during the coming time period if it could.

Aggregate excess demand for cash balances can also be obtained by adding first by commodities instead of by individuals. For an individual good, each person has a net planned purchase or sale, possibly zero in size. Add all these together and we have excess supply of the good, that is, the excess of planned sales over total planned purchases in the community for that good. Again the excess supply may

¹⁶ Goods include all valuable objects except cash. Commodities are goods other than securities. *Op. cit.*, p. 3.

be negative. If we add the money value of these excess supplies over all goods we obtain once more aggregate excess demand for cash balances.

It will be noted that excess demand for cash balances has both a monetary and real connotation; it is defined in terms either of monetary plans or of real plans. This dualism makes ready discussion of real or monetary developments possible. The excess demand for cash balances is also an aggregate of individual plans, so that transition from micro- to macro-statements is singularly easy. Lange has created a device which can be used to discuss the widest variety of economic problems.

FIGURE 1

Lange identifies unemployment with excess demand for cash balances. This is a central point of his analysis. The excess demand for cash balances represents the desires of the community to obtain additional cash in a time period and also equals the sum of excess supplies of commodities. These excess supplies, the excesses of planned sales, define unemployment. Diagrammatically Lange represents excess supply for a particular good in the economy as the quantity $AB = PQ$ in a supply and demand curve chart as shown in Figure 1. This quantity AB represents the surplus of planned sales at the price OC in the whole economy for the particular good. Total unemployment is obtained by adding the values of these quantities for all goods ($\sum OC \times AB$). Some of the excess supplies may be negative, but if the summation is positive, there is unemployment, while a negative excess supply represents an inflationary situation.

What determines excess demand for cash balances? To answer this, Lange considers a basic simple economy of perfect competition, static expectations, and absence of international trade, where the determinants of demand for money can be readily stated. Static expectations mean that each member of the economy acts on the basis that present ruling prices will be future ruling prices. The first thing to notice, Lange argues, is that under these conditions, relative prices are of

secondary importance in the problem of unemployment.¹⁷ The level of excess demand for cash balances is not influenced by relative prices except in so far as they operate through the monetary effect. But, though employment is not affected by relative price changes, it may be affected by the price level itself. For as prices fall, the effective total amount of money in the system is likely to increase and this factor does bear on the employment situation.

It thus turns out that in this initial situation the question of employment depends only on the amount of money in the system. Since relative price questions are secondary in importance, attention can be confined to proportional changes in all prices.¹⁸ In the author's words, the operations of a competitive economy of price flexibility will lead to full employment if, and only if, "a proportional fall in all prices in the economy (interest rates being kept constant and bond prices, consequently, being excepted from the general fall) would reduce the excess demand for cash balances to such an extent that substitution of goods for money takes place."¹⁹ This condition, if satisfied, is labelled a positive monetary effect (of a general price change) by Lange. If a price change makes matters worse, the monetary effect is negative, and if it has no effect, the monetary effect is neutral.

Furthermore, Lange says, in the simple basic economy under analysis, the monetary effect is positive. The law of diminishing returns applies to cash balances. The more one has in terms of its buying power, the more one will spend. Consequently, declines in prices (the real quantity of money increasing) encourages greater expenditures, and hence produces a lower excess demand for cash balances, and less unemployment. In this pleasant pastoral scene all goes well. The conclusion of traditional economics that flexible prices will guarantee full employment is correct, even though its argument was false. Little Peter, the positive monetary effect, can do the job.

¹⁷ This is a crucial point and one on which it is difficult to be absolutely sure about Lange's intention. Since Lange introduces relative prices as a part of his original data and since he admits that with a positive monetary effect, relative price adjustments do affect excess demand for cash balances, it may appear that the statement of the text is false. However, it must be noted that the monetary effect is defined in terms of proportional change in all prices and that the effect of relative prices is inoperative *unless* a positive monetary effect is in operation. The dependence of the Lange argument on homogeneous systems and the association of that argument with the Cambridge cash balance theory also support the statement made above. See Lange, *op. cit.*, pp. 16, 17, 99.

¹⁸ Special attention has to be paid to fixed dollar income obligations, notably to bonds. The fixity of their dollar value keeps their prices tied very closely to money. Thus, a change in all prices really means a change in all prices except of bonds. A decline in prices automatically makes bonds more attractive relative to money, since their real purchasing power increases. Thus bonds and commodities fall equally relative to cash if bond prices remain constant and all other prices fall proportionally. *Op. cit.*, p. 15.

¹⁹ *Ibid.*, p. 7.

But now the scene changes. Into the pastoral scene are introduced the wolves of elastic price expectations, imperfect competition, propensity to consume, capital accumulation, technological uncertainty and factor-saving innovations. How will little Peter fare among these wolves? We soon learn. The only question is which wolf will eat him first.

The bearing of these determinants, elastic price expectations, etc., on the excess demand for cash balances is intricate in detail, but easy to see in broad outline. Elasticity of expectations determines how any change in current prices affects expected future prices. Highly elastic expectations would mean that any changes in prices would be interpreted as significant of further changes and lead to a strong movement toward or away from cash, depending on whether the change in price was down or up. Low propensity to consume makes for an accumulation of cash unless a suitably favorable borrowing and lending process develops to fulfill the desire for saving. Uncertainty acts to make the future bleak and all future transactions unfavorable. It thus encourages the holding of cash, since cash less than any other form of wealth commits the holder to future transactions.

Oligopoly is a little different. Its acts by price-fixing agreement and thus thwarts the effects of price flexibility before it can operate. Factor-saving innovations lower the demand for factors, thus increasing the gap between demand and supply for factors. Capital accumulation exhausts the profitable outlets for investment, thus lowering the demand for cash and contributing directly to the excess demand for cash balances. Such are the main elements of the argument. International trade and policy problems are also considered by Lange, but these are not essential parts of the argument.

The problems which Lange's analysis raises fall naturally into two parts, one the question whether excess demand for cash balances suitably defines unemployment, the second the question whether the alleged determinants satisfactorily define excess demand for cash balances.²⁰

Consider the first of these. Just why, we may ask, does a gap between demand and supply measure unemployment? It is by no means obvious that such a gap defines unemployment, since that gap applies not to events but to plans of economic units. Without further specification of what happens in a disequilibrium situation as distinguished from what people plan to do, it is impossible to know what disequilibrium involves. The *ex ante* definition tells us that excess supply

²⁰ These criticisms concern mainly the consistency of the structure and its relation to traditional thought. Broader methodological questions have been raised by Milton Friedman, in this *Review*, Vol. XXXVI, No. 4 (Sept., 1946), pp. 612-31.

exists in terms of a given price situation, but lacking information as to what happens as regards purchases, sales, and prices, how are we to know what unemployment is *ex post*?

We can see why excess supply might be considered as defining unemployment if we consider a labor market in which the supply curve is intersected by the demand curve at a price below the existing price. The unemployment occurs if the actual amount sold is that demanded at the existing price. The excess supply is idle in fact and hence defines unemployment. The buying parts of plans are carried out, the selling parts are not. One can infer that the same applies to other markets than labor and that unemployment is defined by excess supply generally, because the prevailing price is also the ruling price in which the amount sold is determined by demanders' willingness to buy at that price. In other words, it has been implied that we are dealing with cases of administered prices. Competition is of that particular kind where price adjusts more slowly than quantity.²¹ Disequilibrium culminates not in price adjustments in the first instance, but in quantity sold disappointments. This is implied by Lange, since a contrary interpretation that price adjusts more quickly and that the quantity sold is that which sellers want to sell would not define unemployment. It is only if sellers keep their goods and buyers keep their money that excess demand for cash balances results in unemployment.

The gap between supply and demand at a disequilibrium price can be used as a definition or measure of unemployment only in terms of a particular market analysis. But this market analysis is not supplied. We are given in fact no description of how excess demand for cash balances is carried into unemployment but left to conclude vaguely that because cash is in demand in time of unemployment, it is a sufficient explanation thereof. It cannot be denied that in the real world, periods of unemployment are periods of desire for cash, but that the relation is causal is by no means clear. By neglecting the market mechanism, Lange leaves us with a very incomplete analysis.

There appears, in fact, to be some contradiction in Lange as regards the market mechanism. In his discussion of imperfect competition, Lange suggests that he was not thinking in terms of administered prices under perfect competition along the lines of the above interpretation. He is careful to distinguish imperfect competition from perfect competition on the grounds that supply always equals demand for monopolies whereas under perfect competition it does not. In other

²¹ Whether or not administered prices can fall under the heading of perfect competition is a definitional matter not readily settled. Lange does not define perfect competition and does not face the problem.

words, monopolies meet the fact of excess supply by curtailing sales, in short, by administering its prices. Witness the following:

The removal of the assumption of perfect competition thus introduces the following modification into the picture developed in the preceding chapters. (1) There is no excess demand or excess supply in monopolistic or monopsonistic markets. Disequilibrium in such markets consists in the monopolists selling or the monopsonists buying a quantity different from that which maximizes their profit.²²

Under monopoly we are to picture supply differing from demand at a disequilibrium price maintained until entrepreneurs see fit to adjust the price to more profitable levels. But it is exactly this interpretation of perfect competition that allowed us to identify unemployment with excess supply. So far as market processes are concerned, there seems to be no difference between monopoly and competition, though the contrary is alleged.

We come now to the second basic question, whether the alleged determinants, static expectations, and perfect competition satisfactorily define excess demand for cash balances. The fact is that static expectations are not only insufficient to determine excess demand for cash balances, but are inconsistent with it. The same problem arises as arose in Marshall. If individuals really believe that present prices will continue, they will be able to calculate profits for each line of activity. They will then wish to convert completely into cash or (in most situations) completely out of cash, since some profitable ventures will surely exist in any given disequilibrium price structure. Thus excess demand for cash would be zero. A determinate level of excess demand for cash balances is in fact inconsistent with the initial assumption with which it is discussed.

While this is the most striking instance, other lacks of basic analysis of the market process are evident. For example, what is the relation of business income to personal expenditures, and how are dividend payments fitted into a supply and demand statement? Why are not gaps between supply and demand themselves determinants of plans as well as definers of unemployment? Such questions are not answered. There is no adequate set of assumptions regarding economic behavior, and hence no adequate analysis of the economic process. Except for the recognition of the importance of speculative behavior and of money, no progress is evident over Marshall, and there are evidences of retrogression.

If the basic apparatus of Lange's analysis is accepted, then the formal properties of the effects of elastic price expectations, uncertainty,

²² *Op. cit.*, p. 43.

propensity to consume, etc., on excess demand for cash balances follow in logical fashion in the manner in which Lange has presented them. But, though the logic is correct, some peculiarities about the presentation are worthy of mention. As Lange sees it, curtailment of demand, expansion of supply, and failure of price adjustments to set off the action of the monetary effect will operate to expand excess demand for cash balances. He is thus in a position to emphasize any one of these three factors that he chooses in a kind of *ceteris paribus* arrangement of his own. He is under no obligation to state all possibilities. In some instances he is far from complete. We hear nothing, for example, about how decreased supply can reduce excess demand for cash balances, a result which might well be forthcoming from uncertainty and such influences. The most interesting instance, however, occurs where Lange steps over into the field of classical thought to discuss matters of relative proportions of factors, as he does in connection with innovations and also with capital accumulation. It is interesting to compare the two arguments.

The exhaustion of investment opportunities which Lange feels has occurred in modern economic life can be explained in classical terms. Capital goods are subject to diminishing returns, and every increment to their stock reduces their worth. Witness ". . . an increase in the stock of (some or all) investment goods that is not accompanied by a proportional increase in the supply of primary factors leads to a decline in the marginal physical productivity of the former."²³ This is an argument based on classical theory of proportions of factors. The higher the proportions of capital to factors in the production process, the lower the marginal productivity of capital. This means that interest rates fall since the demand for funds depends on the productivity of capital. In the classical treatment of this point, the argument develops that as the proportion of capital increases, the marginal productivity of labor rises, and wages rise. Lange does not follow the classical argument this far, however; rather he emphasizes that as the demand for capital falls, there is unemployment and a decline in wages. After this the results depend on the nature of the monetary effect.

Lange has another argument based on proportions of factors in connection with factor-saving innovations. An important case is that fewer primary factors (labor) may be required as the result of innovation. In such case the effect of the innovation is to create a relative excess of primary factors, thus throwing people out of work. Unemployment results, hence falling prices, with good or evil resulting depending upon the nature of the monetary effect. The argument is just like the one regarding capital accumulation. Here the factor-saving innovation

²³ *Op. cit.*, p. 67.

creates excess supply of laborers, whereas capital accumulation created a shortage of laborers. It would seem that the factor-saving innovation is just the thing that is needed to prevent the excess proportion of capital. The failure of the "supply of primary factors" which Lange speaks of in the capital accumulation argument seems to find a friend in factor-saving innovations. Lange, however, notes no connection between the two arguments. In one case the accumulation gave rise to an excess of capital which stopped investment and caused unemployment. In the other case, the innovation gives rise to excess labor supply and causes unemployment. Either way the result is bad in this diabolical world.

We conclude that the basic problems unanswered in Marshallian economics have not been answered by Lange. What are the basic determinants of economic behavior, and what are their implications to economic life? On these questions little light is shed. An effort has been made to state behavior in terms of the propensity to accumulate cash, but the manner in which this propensity is related to operations of the economic world has not been made clear.

VII

Lange has asserted (developing a theme of Keynes) that classical economics is inherently incapable of treating problems of trade fluctuations and monetary developments. He purports to develop a theory of these problems adequate to reveal the inherent classical constraint. An examination of Lange's work does not support this claim. An examination of parts of classical doctrine does not reveal such inherent constraint.

In Marshall's work we see an effort to state a general economic theory involving all elements of economic life. Many of the elements of a sound dynamic and monetary economics are included. The trouble is that the description is vague and incomplete at many points. The effort, however, is obviously to see how the economic system works in non-equilibrium situations. There seems to be no obstacle to completing this system except the intellectual labor required.

The seeming divorce of classical and monetary thought can be seen in works where the back is turned on uncertainty, and equilibrium becomes the subject of discussion. In Knight this is done by design. In Hicks it appears to happen unknown to the author. The essential factor preventing these works from dealing adequately with problems of unemployment is the lack of definitive statement of behavior under uncertainty. This rather than partial or general equilibrium questions is the crucial matter.

Lange's work intended as an analysis of the limitations of classical

thought ends as tribute to its usefulness in monetary analysis. Its basic failure is inherited from Marshall, a failure to state the behavioristic assumptions definitely. It is, however, a poorer work than Marshall's in that the essential lacks are covered with analytical superstructure. Classical methods of market analysis are used extensively although with some inconsistency of argument.

No natural barrier between classical and monetary thought exists. On the contrary, the different approaches are supplementary. Classical thought contains and requires monetary notions. Monetary economics requires individual market analysis. The points of departure of the different systems are perhaps different, but there is no reason to believe that when the best monetary system and the best classical system have been written they will differ in subject matter or conclusion.

MARKET STRUCTURE AND MONOPOLY POWER¹

By ANDREAS G. PAPANDREOU*

I

The increasing tempo of successful prosecutions of violators of our antitrust legislation is once more bringing to our attention the relationship between market or industry types and monopoly power. This may well provide a badly needed opportunity for a general reconsideration, extension and modification of some generally held concepts regarding this relationship, in the light of recent theoretical contributions.² Among the problems which call for serious study are those which relate to the unbridged gap between the economic and the legal concepts of monopoly and competition. Pioneer work has already been done in this area,³ but it does not go beyond the initial stage of breaking the path for further research.

One important reason for this gap between the legal and economic concepts of monopoly is their difference in emphasis. Whereas the lawyer deals with competitive relationships, the economist is primarily interested in the allocation mechanism and welfare economics. To put it in somewhat different terms, the economist is primarily concerned with the power relationships between sellers *and* buyers, and the manner in which these relationships may affect the operation of the allocation mechanism and interfere with the "perfectness" of competition; the lawyer, on the other hand, is primarily concerned with the power relationships between sellers *or* between buyers, and the manner in which these relationships may affect the "freedom" of competition. Both approaches are of course legitimate. We must recognize, in fact, that there are many ways of looking at a firm's power within a given market structure. Despite the fact that all relate to a firm's position (or behavior) in the market, they focus on different aspects of the complex set of relationships between sellers, between buyers, and between sellers and

* The author is associate professor of economics at the University of Minnesota.

¹ The paper is restricted to the study of monopoly power in selling. It should not be difficult to extend the conclusions reached in this paper to the study of monopoly power in buying.

² See Joseph Schumpeter, *Capitalism, Socialism and Democracy* (New York, 1942), pp. 81-106.

³ See E. S. Mason, "Monopoly in Law and Economics," *The Yale Law Journal*, Vol. 47 (1937), pp. 34-39, reprinted in *Readings in the Social Control of Industry* (Philadelphia, 1942), pp. 25-47.

buyers, which are present in every market structure. We may attempt to define and measure a firm's power over the buyers of its products, or over its competitors in selling, or over its competitors in buying, or over the economy as a whole. In all these cases we are dealing with the same set of structural facts, but isolate some particular aspect of the set for definition and measurement.

Professor Abba P. Lerner's⁴ definition and measure of monopoly power is typical of the economist's approach to the problem. According to Professor Lerner "... the mark of the absence of monopoly is the equality of price or *average* receipts to *marginal* costs, . . ."⁵ His approach runs in terms of welfare economics, and his index of monopoly power, Price—Marginal Cost/Price, is most appropriate in the analysis of the effects of monopoly on the allocation of resources. Attempts to use this index of monopoly power in dealing with problems not involving the allocation mechanism have not been particularly successful.⁶

Measures focusing on different aspects of monopoly power have been suggested by economists, but none has been as popular with the profession as the Lerner index. A measure of supernormal profits has been proposed by Professor Bain.⁷ It is based on the discrepancy between price and average cost. Such a discrepancy, Professor Bain claims, "is significant because of its influence directly on the functional distribution of income, and indirectly on the propensity to consume, the level of employment, etc."⁸ This measure, however, must be used very carefully. It does not pertain to monopoly power *stricto sensu*, but "lumps together the effects of monopoly, monopsony, limit to entry, and . . . also to some extent, the effects of frictional forces in a competitive system, like ignorance and special degrees of uncertainty."⁹

⁵ *Ibid.*, p. 161.

⁶ See M. Kalecki, "The Determinants of the Distribution of the National Income," *Econometrica*, Vol. 6 (1938), pp. 97-112; R. H. Whitman, "A Note on the Concept of 'Degree of Monopoly,'" *Econ. Jour.*, Vol. LI (1941), pp. 261-69, and M. Kalecki, "'Degree of Monopoly'—A Comment," *Econ. Jour.*, Vol. LII (1942), pp. 121-27. For an attempt to measure changes in the degree of monopoly power, along the lines suggested by Lerner, see J. T. Dunlop, "Price Flexibility and the Degree of Monopoly," *Quart. Jour. Econ.*, Vol. LIII (1939), pp. 522-34, and R. S. Tucker, "The Degree of Monopoly," *Quart. Jour. Econ.*, Vol. LIV (1940), pp. 167-69.

⁷ J. S. Bain, "The Profit Rate as a Measure of Monopoly Power," *Quart. Jour. Econ.*, Vol. LV (1941), pp. 271-93.

⁸ J. S. Bain, "Measurements of the Degree of Monopoly: a Note," *Economica*, (new series) Vol. 10 (1943), p. 66. The reader should keep in mind that Professor Bain rectifies average cost "to a certain opportunity level," and that his "profit rate" is derived from the "accounting profit rate" by certain estimates as to the market value of capital assets which would be held under competitive conditions.

⁹ K. W. Rothchild, "A Further Note on the Degree of Monopoly," *Economica*, (new series) Vol. 10 (1943), p. 69.

Another, and one which is more significant from the point of view of this paper, is the measure suggested by Mr. Rothchild.¹⁰ The degree of monopoly power, according to this author, is equal to the ratio of the slope of the "species" demand curve to the slope of the "genus" demand curve.¹¹ This measure focuses on the position of the firm vis-à-vis its competitors in the market, and, therefore, comes closer to the concepts of monopoly present in most industry studies, court decisions, and government reports, than either the Bain or the Lerner measures. Recently a most interesting measure, which emphasizes similar aspects of monopoly power, has been proposed by Professor Morgan.¹² The Morgan measure consists of a coefficient of *insulation* of the firm from competition, which is expressed as an increasing function of the firm's relative size, and as a decreasing function of the substitutability of the products of its competitors for the firm's product. This coefficient is clearly directed toward defining and measuring a firm's power vis-à-vis its competitors.

My objective in this paper consists in developing a comprehensive set of concepts dealing with monopoly power in terms of competitive relationships, and further, in associating types of market structure with types of monopoly power. The formulation of these concepts will be carried out in a manner which is intended to narrow the gap between legal and economic concepts. I should like to state emphatically, however, that the concepts developed in this paper in no way displace concepts already in use; rather they are meant to supplement them by shifting the emphasis to an aspect of monopoly power which has not been treated sufficiently by economic theorists.

II

The very nature of the purpose of this paper calls for an unambiguous definition of the concept of industry. Before the advent of the theory of monopolistic or imperfect competition, the concept of a "group" of firms competing in the sale of a "commodity" was considered self-explanatory.¹³ The pre-"monopolistic competition" concept of industry

¹⁰ K. W. Rothchild, "The Degree of Monopoly," *Economica*, (new series) Vol. 9 (1942), pp. 21-39.

¹¹ The "species" and "genus" demand curves are synonymous with Professor Chamberlin's dd' and DD' curves. dd' is the sales curve confronting the firm on the assumption that *all* other prices are given. DD' is the sales curve confronting the firm on the assumption that the prices of the firm's competitors are changed in the same or some other systematic way as the firm's in question.

¹² Theodore Morgan, "A Measure of Monopoly in Selling," *Quart. Jour. Econ.*, Vol. LX (1946), pp. 461-63.

¹³ This should not be interpreted to mean that economists never took into account the intricacies of the concept. See, for instance, Alfred Marshall's *Principles of Economics* (8th ed., London, 1920), p. 100, n. 1.

referred essentially to a group of firms selling a "physically" identical product. Since the advent in 1933 of the theory of monopolistic competition,¹⁴ however, the concept has been subjected to thorough scrutiny. Both Mrs. Robinson and Professor Chamberlin use the concept of "group" or "industry" with careful qualifications and explicit skepticism. For Mrs. Robinson "an industry is any group of firms producing a single commodity. The correspondence of such an industry to the industries of the real world is not perhaps very close. But in some cases, where a commodity in the real world is bounded on all sides by a marked gap between itself and its closest substitutes, the real-world firms producing this real-world commodity will conform to the definition of an industry sufficiently closely to make the discussion of industries in this technical sense of some interest."¹⁵ For Professor Chamberlin the "group" concept is merely an analytical tool which derives its content from the problem at hand. "Almost any general class of products divides itself into sub-classes. . . . Evidently, a group may be large or small, depending upon the degree of generality given to the classification, but even if it is large, if subgroups exist, this fact cannot be disregarded."¹⁶ Elsewhere, he arrives at the conclusion that "one emerges from any attempt to classify industries . . . with a feeling that it is all exceedingly arbitrary. The 'common sense' definitions of industries in terms of which practical problems are likely to be studied seem to be based much more upon technological criteria than upon the possibility of market substitution."¹⁷

Kaldor considers the "group" definable only from the point of view of an individual seller.¹⁸ The "industry" of firm i , then, overlaps but is not necessarily identical with the "industry" of a competing firm j , and it becomes conceivable that there may be as many "industries" as there are firms. For Dr. Triffin the industry concept is obsolete for strictly theoretical purposes, although it may be of some use for empirical studies.¹⁹

The author fully concurs with the general skepticism that envelops the concept of a "group" or "industry." It must be admitted that the concept is not universally useful, and that it may, in fact, hamper theo-

retical formulations of the Walrasian variety. The concept may, however, be useful in theoretical as well as in empirical-statistical studies whose scope is substantially narrower than the whole economy. The grouping of firms for purposes of statistical description or behavior analysis is fully justified, provided that the definition of the "group" is meaningful for the problem at hand and consistent throughout the study or analysis.

The concept of a group of firms selling substitute products is crucial for the purposes of this paper. There remains the question, however, whether we should use the (Kaldor) concept of a *firm-centered* industry or the traditional concept of a *group-centered* industry. The firm-centered industry concept is more elegant. *Industry from the point of view of firm i may be defined to include all firms which compete in selling with firm i .*²⁰ In this paper, nevertheless, the concept of a group-centered industry will be adopted. Despite its nebulous character, it corresponds more closely to the "industry" of empirical-statistical studies than does the concept of a firm centered industry.²¹ *Our group-centered industry concept is defined to include all the firms which compete in selling with one another.*²² Two observations are in order in connection with this definition. First, it must be recognized that the boundary of an industry, as it is defined in this paper, is "fuzzy." Some firms within the group may compete with firms outside of the group; they may, in fact, belong to other industries as well as to the industry under consideration. In order to simplify the argument, we will assume in what follows that no industry or market overlapping is present. Removal of this assumption would not destroy any of the results; it would merely make their formulation somewhat more complex. Secondly, an industry, as it is defined in this paper, is much more inclusive than is appropriate for the purposes of most investigators and analysts. As we approach concrete situations we may find it useful to raise the value of the cross-elasticity coefficient which, for our given purposes, makes two firms significantly competitive. This procedure is perfectly legitimate, provided it is meaningful for the situation or problem under study.²³

²⁰ Two firms i and j may be said to compete in selling if the cross-elasticity of demand for the product of firm i in terms of the price of the product of firm j is greater than zero.

²¹ The selection of the group-centered industry concept for use in this paper is due in part to an attempt to maintain a certain measure of comparability between the concepts generally held and the conclusions reached in this paper.

²² This group must in fact fulfill two conditions: (a) any two firms in the group must compete, and (b) no firm must be left out of the group if it competes with all the firms in it.

²³ For further discussion of the concept of industry see J. S. Bain, *Economics of the Pacific Coast Petroleum Industry* (Berkeley, 1944), Part I, pp. 10-11, and *Pricing, Distribution and Employment* (New York, 1948), pp. 10-60; G. Stigler, *The Theory of Price* (New York, 1946), pp. 280-83; F. Machlup, "Competition, Pliopoly and Profit, Part I," *Economica* (new series), Vol. 9 (1942), pp. 1-23, but especially pp. 5-7.

III

The purpose of the investigator or analyst determines the selection of criteria for the classification of market or industry types, in the same manner that it determines the content of his industry concept. For an analysis of firm behavior the *differentia specifica* of market or industry types is to be found in the character of the competitive relationships among the firms in an industry or market. The widely held classification of industry types in terms of *numbers* and *product-differentiation*²⁴ is not fully satisfactory from this point of view. It reflects *indirectly* only the character of relationships among the firms comprising the industry. *How large* must the number of firms in an industry be in order that it may fall in the category of a large-number-of-firms industry? The answer is simple, but it does not run in terms of numbers. The number must be so large that firms cannot influence one another's volume of sales by cutting price. Under such conditions firms behave without taking into account the underlying interdependence of their behavior. As Professor Machlup has put it, "the criterion of polypoly is not simply 'large numbers,' but it is, instead, a state of mind and a type of behaviour which is usually associated with large numbers of sellers in a market. . . . Thus, a subjective habit or disposition of certain individuals is the essence of the concept of polypoly."²⁵ One might add that numbers and product-differentiation necessarily restrict the classification of industry types to the five well-known limiting cases. They lack the flexibility which is necessary in dealing with real-world situations.

Dr. Triffin's concepts of *circularity* and *atomicity* come much closer to the heart of the matter than do the concepts of *small* and *large* numbers.²⁶ The essence of circular interdependence between two firms is the "boomerang-like" character of their behavior vis-à-vis one another; and the essence of atomistic interdependence between two firms is the absence of this "boomerang-like" character from their behavior vis-à-vis one another. This is clearly a much more effective criterion than numbers for the classification of market or industry types. It does not merely come closer to the heart of the matter; it is also capable of describing complex real-world situations.

Dr. Triffin's definition and use of these concepts, however, is not particularly satisfactory. Not only does he offer two different definitions

²⁴ F. Machlup, "Monopoly and Competition: A Classification of Market Positions," *Am. Econ. Rev.*, Vol. XXVII (1937), pp. 445-51. For a somewhat different, more extended treatment, see J. S. Bain, "Market Classification in Modern Price Theory," *Quart. Jour. Econ.*, Vol. LVI (1942), pp. 560-74.

²⁵ F. Machlup, "Competition, Pliopoly and Profit, Part I," *Economica* (new series) Vol. 9 (1942), p. 2.

²⁶ R. Triffin, *op. cit.*, pp. 104, 115-16, 143.

of circularity,²⁷ but he does not succeed in differentiating clearly between the two pairs of concepts of *homogeneity-heterogeneity* and *atomistic-circularity*. It is indeed impossible to define pure competition (Dr. Triffin's atomistic homeopoly) in terms of cross-elasticity of demand in a manner which keeps it distinct from its antithesis, *i.e.*, pure monopoly.²⁸ According to Dr. Triffin's classification, if firm *i* is a pure monopolist, the cross-elasticity of demand for its product in terms of the price of the product of any other firm *j* becomes zero; if firm *i* is in pure competition with firm *j*, the cross-elasticity of demand for the product of firm *i* in terms of the price of the product of firm *j* becomes infinite. Yet it should be obvious that, under conditions of pure competition, it is impossible for firm *j* to affect the *actual* volume of firm *i*'s sales. If it could do so, firm *i* should also be considered capable of affecting the sales of firm *j*, and the relationship would indeed be circular rather than atomistic, which contradicts our assumption that the situation is purely competitive. In a purely competitive situation, the cross-elasticity of demand for the product of firm *i* in terms of the price of the product of firm *j* becomes zero, *in terms of actual or realizable changes in the volume of firm i's sales*. On these grounds, however, we should consider every pure competitor as being a pure monopolist! It seems impossible, therefore, to distinguish between pure competition and pure monopoly on the basis of Dr. Triffin's criterion.

A distinction between two related but different concepts seems to be needed if we are to salvage the concept of cross-elasticity of demand for purposes of market classification and measurement of monopoly power in terms of competitive relationships. We should restrict the coefficient of cross-elasticity of demand to *potential* changes in the volume of a firm's sales, and coin a new coefficient to associate *realizable* relative changes in the volume of a firm's sales with relative changes in the prices of the products of other firms. The cross-elasticity coefficient measures potential changes in the sense that it depicts only the readiness of *de-*

²⁷ On page 104 he defines the relationship between two firms *i* and *j* as circular, if the two partial derivatives

$$\frac{p_j \delta q_i}{q_i \delta p_j} \quad \text{and} \quad \frac{q_i \delta p_j}{p_j \delta q_i}$$

are both greater than zero. (*q* refers to quantity sold and *p* to price.) On pages 115-16, however, he defines the relationship between firms *i* and *j* as circular, if

$$\frac{\delta \pi_i}{\delta p_j} \quad \text{and} \quad \frac{\delta^2 \pi_i}{\delta p_j \delta p_i}$$

are both positive. (π stands for profits.) For a critical review of Dr. Triffin's concepts see S. Weintraub, "The Classification of Market Positions: Comment," *Quart. Jour. Econ.*, Vol. LVI (1942), pp. 666-73, and E. F. Beach, "Triffin's Classification of Market Positions," *Canadian Jour. Econ. and Pol. Sci.*, Vol. IX (1943), pp. 69-74.

²⁸ See E. F. Beach, *op. cit.*, p. 71, and Morgan, *op. cit.*, p. 461, n. 3.

mand units to shift from one seller to another, following a price change. The new coefficient should take into account the capacity of the firm which attracts demand units by cutting price to match them with *supply units*. This new coefficient may be called the *coefficient of penetration*, inasmuch as it measures the capacity of a firm to cut into the volume of another firm's sales by reducing price. In order to define clearly the meaning of this new coefficient, and to indicate its relationship to the coefficient of cross-elasticity we must resort to symbolic presentation.

Let $q_i = f_i(p_i, p_j, P_{N''})$ be a simplified form²⁹ of the demand function for the product of firm i . q_i stands for the volume of product of firm i demanded, p_i for the price of the product of firm i , p_j for the price of the product of firm j , and $P_{N''}$ for the "price" of all the other firms in the industry.³⁰ The *cross-elasticity of demand* for the product of firm i in terms of the price of the product of firm j , then, is

$$N_{q_i p_j} = \frac{p_j}{q_i} \cdot \frac{\partial}{\partial p_j} f_i(p_i, p_j, P_{N''}).$$

The *coefficient of penetration* of firm j into the market of firm i may be defined as

$$R_{q_i p_j} = K_j \left\{ \frac{p_j}{q_i} \cdot \frac{\partial}{\partial p_j} f_i(p_i, p_j, P_{N''}) \right\} = K_j N_{q_i p_j}$$

where K_j is a factor which may assume any value between zero and unity, including both, ($1 \geq K_j \geq 0$).

K_j is, in fact, an index of the capacity of firm j to match with supply units the demand units which stand ready to shift to it following its price change.³¹ It will be readily admitted that this concept of an index of the capacity to match (with supply units) increases in quantity demanded following a price cut, is most awkward. It is nevertheless a very important tool in the study of competitive relationships. It may be thought of as a function of the price elasticity of demand for the product of the price-cutting firm, and of the elasticity of an output-outlay function. Symbolically:

$$K_j = \phi_j \left(\frac{p_j}{q_j} \cdot \frac{\partial}{\partial p_j} f_j(p_j, P_{N''}), \frac{z_j}{q_j} \cdot \frac{d}{dz_j} F_j(z_j) \right).$$

²⁹ The function is simplified because it leaves out all independent variables other than prices, and also because all prices (other than the prices of i and j) have been grouped into a single independent variable $P_{N''}$.

³⁰ $P_{N''}$ may be taken as the weighted average price of all the firms in the industry (other than i or j), on the assumption of an unchanging price-structure.

³¹ All the measures refer to price cuts rather than price changes. Since we are formulating them in terms of instantaneous rates of change, however, the distinction loses its importance.

where $q_j = f_j(p_i, p_j, P_{N''})$ is a simplified form of the demand function for the product of firm j , and $q_i = F_j(z_j)$ is the output-outlay function of firm j .³² The price elasticity of demand for the product of firm j is a measure of the responsiveness of the quantity demanded to changes in its price, whereas the elasticity of the output-outlay function is a measure of the firm's capacity to expand output to match the increases in the quantity demanded following a price cut. These two elasticities determine between them the value of K_j .³³ Although we do not know much about the shape of ϕ , we do know that k is an increasing function of the elasticity of the output-outlay function and a decreasing function of the elasticity of demand.

It becomes possible now to define certain limiting cases of market or industry types, in terms of the coefficient of cross-elasticity of demand and the coefficient of penetration. I will restrict myself to the discussion of the well-known *symmetrical* cases, in order to avoid making the argument unduly complex. This classification of market structures will run in terms of homogeneity *versus* heterogeneity,³⁴ and atomicity *versus* circularity in competitive relationships. Atomicity and circularity must be defined before we can proceed: *Two firms are atomistically competitive if either one is incapable of penetrating the other's market. Two firms are circularly competitive if both are capable of penetrating each other's market.*³⁵ Since we restrict the discussion to symmetrical cases, the situation in which firm j is able to penetrate firm i 's market, but firm i is incapable of penetrating firm j 's market, is automatically excluded. We may now proceed with the classification:

(a) *Atomistic Homeopoly:*

It may be defined as the market structure of an industry in which any two firms i and j are homogeneously and atomistically competitive. Symbolically:

³² The output-outlay function is merely the *inverse* of the total cost function.

³³ There remains, of course, the very thorny question of the nature of this output-outlay function. Both $Nq_i p_i$ and $Rq_i p_i$ involve instantaneous relative rates of change. So does $z_j/q_i \cdot dq_i/dz_j$. But is $F_j(z_j)$ a "market period," a "short-run" or a "long-run" function? The demand functions involved must needs refer to an instant of time. They incorporate the structure of interdependencies existing at an instant of time. But if $F_j(z_j)$ were to refer to the "market period," its elasticity with respect to outlay would be nil. A "short-run" output-outlay function (involving the usual assumptions of fixed plant and equipment) seems to make more sense for the problem at hand. This discrepancy between the time-dimension of the demand functions and the time-dimension of the output-outlay function is not damaging, however, to this purely abstract formulation.

³⁴ Two firms i and j may be said to compete homogeneously if $Nq_i p_i = \infty$; they compete heterogeneously if $\infty > Nq_i p_i > 0$.

³⁵ It must be emphasized that the definitions given to atomicity and circularity in this paper differ from those of Dr. Triffin.

$$N_{q_i p_j} = \infty$$

$$R_{q_i p_j} = 0$$

$$R_{q_j p_i} = 0.$$

(b) *Atomistic Heteropoly:*

It may be defined as the market structure of an industry in which *any* two firms *i* and *j* are heterogeneously and atomistically competitive. Symbolically:

$$\infty > N_{q_i p_j} > 0$$

$$R_{q_i p_j} = 0$$

$$R_{q_j p_i} = 0.$$

(c) *Circular Homeopoly:*

It may be defined as the market structure of an industry in which *any* two firms *i* and *j* are homogeneously and circularly competitive. Symbolically:

$$N_{q_i p_j} = \infty$$

$$R_{q_i p_j} > 0$$

$$R_{q_j p_i} > 0.$$

(d) *Circular Heteropoly:*

It may be defined as the market structure of an industry in which *any* two firms *i* and *j* are heterogeneously and circularly competitive. Symbolically:

$$\infty > N_{q_i p_i} > 0$$

$$R_{q_i p_j} > 0$$

$$R_{q_j p_i} > 0.$$

(e) *Pure Monopoly:*

It may be defined as the market structure of an industry in which competition is totally absent. Firm *j* is a pure monopolist if the cross-elasticity of demand for its product in terms of the price of the product of *any* other firm *i* in the economy becomes zero.

It should be stated again that the five cases discussed are limiting cases. The discussion could be extended indefinitely if we considered asymmetrical cases, which, of course, abound in actuality.

IV

We are ready now to turn to the formulation of measures of monopoly power in terms of the structure of competitive relationships. Let us se-

lect a firm j and attempt to measure its power vis-à-vis its competitors.³⁶ A firm's capacity to penetrate its competitors' markets is *specific*, i.e., it relates to individual competitors' markets separately, and cannot, therefore, be given a general expression. The whole list of penetration coefficients of a firm (say j) into the markets of its competitors (say $a, b, c, \dots i, \dots n$) is required if we are to obtain a balanced picture of its position in the market.

$$R_{qa pj}, R_{qb pj}, R_{qc pj}, \dots R_{qi pj}, \dots R_{qn pj}.$$

The coefficient of penetration, however, is only the first of the required measures. It measures the capacity of firm j to penetrate its competitors' markets. Firm j 's monopoly power vis-à-vis its competitors is not limited to its capacity to penetrate their markets. Its capacity to withstand attacks on their part is equally important. We need, then, a coefficient of insulation which will measure the degree of non-responsiveness of the actual volume of sales of firm j to price cuts initiated by its competitors. The structure of this coefficient of insulation is obvious only in the limiting case of homogeneous competition among firm j 's competitors. When competition among them is homogeneous, the cross-elasticity of demand for the output of firm j in terms of P_N ,³⁷ is equal to the cross-elasticity of demand for the output of firm j in terms of the price of any of its competitors (say firm i). Symbolically:

$$N_{qj} P_{N'} = N_{qj pi}, \quad \text{if} \quad N_{qj ph} = \infty,$$

where i and h are *any* two firms, other than j , in firm j 's industry. The coefficient of insulation of firm j from competition, in this limiting case, is merely the reciprocal of the coefficient of penetration of its competitors, treated as a single firm, into firm j 's market.

We are entitled to treat N' firms as a unit, however, only because they are competing homogeneously.³⁸ The problem becomes somewhat more complex when the competition among N' firms is heterogeneous. Under conditions of heterogeneous competition among N' firms we must sum the separate penetration coefficients of N' firms in order to obtain the over-all coefficient of penetration of N' firms into firm j 's market. This process of summation is not simple. The capacity of any firm i , among N' firms, to penetrate firm j 's market, when firms N' reduce prices simultaneously, may be substantially greater than its capacity to penetrate firm j 's market when it alone reduces its price.

³⁶ The formulations which follow are independent of the type of industry concept selected. They are valid whether we adopt the firm-centered or the group-centered industry concept.

³⁷ P_N stands for the weighted average prices of all the firms in the industry other than j , on the assumption of a constant price-structure.

³⁸ Professor Morgan's measure is implicitly based on this assumption.

This is due to the fact that K_i may assume different values in the two cases; in fact it may assume a much larger value in the former case than it does in the latter. We have seen that K_i is a decreasing function of the elasticity of demand for the product of firm i . The elasticity of demand for firm i 's product is normally lower in terms of $P_{N'}$ than it is in terms of p_i , inasmuch as the elasticity of a "genus-type" curve is normally lower than the elasticity of a "species-type" demand curve.³⁹ This should explain the difference between the two values of K_i , and, therefore, the difference between the two penetration coefficients of firm i in the two situations. Symbolic presentation will clarify the argument. In order to avoid confusion, however, it seems best to adopt a new set of symbols for the formulation of the coefficient of insulation.

We may substitute λ for K and ρ for R in the formulation of the coefficient of penetration of firm i into firm j 's market, when N' firms reduce their prices simultaneously.

$$\rho_{q_j p_i} = \lambda_i N_{q_j p_i}$$

where

$$\lambda_i = \psi_i \left(\frac{P_{N'}}{q_i} \cdot \frac{\partial}{\partial P_{N'}} g_i(p_j, P_{N'}), \frac{z_i}{q_i} \cdot \frac{d}{dz_i} F_i(z_i) \right)$$

and $q_i = g_i(p_j, P_{N'})$ stands for a (simplified) "genus-type" demand function for the product of firm i . From this it follows that $\lambda_i \geq K_i$ and that $\rho_{q_j p_i} \geq R_{q_j p_i}$. $R_{q_j p_i} = \rho_{q_j p_i}$ in the limiting case where firm i is the single competitor of firm j .

It is legitimate now to sum the ρ 's of firms N' and take its reciprocal as the coefficient of insulation of firm j . Symbolically the coefficient of insulation of firm j may be defined as

$$L_{q_j P_{N'}} = 1 / \sum_{i=1}^{N'} \rho_{q_j p_i}$$

V

Neither R nor L lend themselves easily to measurement. This, of course, is not peculiar to these concepts. All suggested measures of monopoly power are more or less subject to this limitation. Fortunately, however, R and L may be employed in an *ordinal* sense to describe the structure of the balance of power in an industry or market. This should not be taken to mean that we can dispense entirely with *cardinal* measures. We still need to know something concerning the "whereabouts" of R and L . More specifically, we need to know whether they become

³⁹ See note 11.

zero or infinite or tend to assume a finite positive value. Once we know this much about the absolute values of the coefficients, we may turn to their ordinal values. An example may clarify this statement. Let us assume that in an industry comprising three firms (i, j , and k) all the coefficients assume a finite positive value. Symbolically:

$$\begin{array}{rcl} & R_{q_i p_j} > 0 & \\ \sim & & L_{q_j p_{N'}} > 0 \\ & R_{q_k p_j} > 0 & \\ & R_{q_j p_i} > 0 & L_{q_i p_{N'}} > 0 \\ & R_{q_k p_i} > 0 & \\ & R_{q_j p_k} > 0 & L_{q_k p_{N'}} > 0. \\ & R_{q_i p_k} > 0 & \end{array}$$

This is just another way of saying that all firms are insulated to some extent, and that all the firms are capable of penetrating one another's market to some extent. If now, in addition to this, we can say that

$$R_{q_i p_k} > R_{q_j p_k} > R_{q_i p_j} > R_{q_j p_i} > R_{q_k p_j} > R_{q_k p_i}$$

and that

$$L_{q_k p_{N'}} > L_{q_j p_{N'}} > L_{q_i p_{N'}}$$

we have a good understanding of the most important aspects of the structure of the balance of power in this industry. Exact cardinal measures would not add substantially to our knowledge.

Intelligent guessing based on information concerning substitutability among products, shares of the market represented by each firm's sales, and degrees of plant and equipment utilization by the firms in the industry, should enable the investigator to arrive at a meaningful description of the structure of monopoly power in the industry. Even limited information concerning product substitutabilities should make it possible for him to assign to cross-elasticities a value of zero or infinity, or to arrive at the conclusion that the cross-elasticity assumes a finite positive value. Finally, even limited information concerning firm's shares of the market and degrees of plant and equipment utilization should enable him to make tolerable approximations to the values of k .⁴⁰ From there on the task of describing, in terms of the R and L

⁴⁰ Other things being equal, k must be an increasing function of the share of the market represented by a firm's sales and a decreasing function of the degree of plant and equipment

coefficients, the structure of monopoly power prevalent in the industry should not prove exceedingly difficult.

Inasmuch as k may be thought of as an increasing function of the share of the market represented by a firm's sales,⁴¹ we are entitled to say that both R and L are increasing functions of the share of the market represented by a firm's sales. On the other hand, whereas R is an increasing function, L is a decreasing function of the cross-elasticity of demand. It follows that no firm can ever possess both aspects of monopoly power, vis-à-vis its competitors, to the maximum degree. In the case of pure monopoly, for instance, L becomes infinite, whereas R becomes zero. It may not be amiss to indicate briefly the value or the range of values of the two coefficients for a firm (say firm j) within the various *symmetrical* limiting cases of market structures.

(a) *Atomistic Homeopoly*:

$$R_{q_i p_j} = 0, \quad L_{q_j P_N} = 0.$$

(b) *Atomistic Heteropoly*:

$$R_{q_i p_j} = 0, \quad \infty > L_{q_j P_N} > 0.$$

(c) *Circular Homeopoly*:

$$R_{q_i p_j} > 0, \quad \infty > L_{q_j P_N} \geq 0.$$

(d) *Circular Heteropoly*:

$$R_{q_i p_j} > 0, \quad \infty > L_{q_j P_N} > 0.$$

(e) *Pure Monopoly*:

$$R_{q_i p_j} = 0, \quad L_{q_j P_N} = \infty.$$

VI

Some may raise the objection that these measures of monopoly power and criteria for market structure classification are based exclusively on price competition, and do not take into account the effects that changes in selling outlay and product variation on the part of a firm may have on the sales volume of another firm. Dr. Triffin admits the validity of a similar objection to his study. "A price classification, as the one proposed in this study, is by no means exhaustive and, strictly speaking, it should be complemented with similar classifications based on other strategic factors in business competition."⁴² I can agree with Dr. Triffin

utilization. This follows from the fact that k is a decreasing function of the price-elasticity of demand and an increasing function of the elasticity of the output-outlay function.

⁴¹ See previous note.

⁴² *Op. cit.*, p. 98, n. 1.

only if it is assumed that the demand for a firm's product is a continuous function of the "product"⁴³ and selling outlay incurred by the firm as well as of the "products" and selling outlays of its competitors. In these circumstances "product" and selling outlay cross-elasticities would be meaningful measures. Such an assumption, however, is most dangerous. Fundamental changes in sales policies and radical alterations of the product are innovational in character, and would cause abrupt *shifts* of the demand functions. Such shifts constitute changes in the *market balance of power*. Changes in the market balance of power, however, imply alterations of the market structure; they raise questions of transition from one to another type of market structure, and, therefore, defy any descriptive and classificatory attempt. Can we distinguish between innovational product and sales policy changes and non-innovational variations of the "product" or selling outlay? Unless we can do so, it seems futile to attempt to extend our analysis to include product variation and selling outlays. Price cross-elasticities are ideally suited for our purpose, since they bring out the interdependencies inherent in a *given* market structure and no more.⁴⁴

One additional comment is in order. The measures of monopoly power presented in this paper constitute "snapshots" of the structure of power relationships prevalent at a given instant within a system of firms. It must be recognized, of course, that competitive firm behavior elicits continuous changes in the power structure within an industry and may at times lead to spectacular transitions from one market type or position to another. In so far, in fact, as such firm behavior is conditioned by the structure of power relationships in the immediate environment of the firm, there is a dynamic or evolutionary nexus between structure and behavior which constitutes the flesh and blood of the competitive process. The analysis of this process lies, of course, outside the scope of this paper.⁴⁵

⁴³ This presupposes, of course, that we have been successful in quantifying the "product" variable.

⁴⁴ We must be careful, however, even when we deal with price cross-elasticities. Only *point* cross-elasticities bring out the interdependencies inherent in a *given* market structure. *Arc* cross-elasticities involve changes in the structure of balance of power in the market.

⁴⁵ It may not be amiss to indicate the manner in which the concepts developed in this paper may be put to use in interpreting our antitrust legislation. The Sherman Act, for instance, takes on a much clearer meaning for the economist when couched in terms of the concepts presented in this paper, than it would otherwise possess. Section 2 makes it illegal for any firm (or group of firms) to make use of its (their) aggressive (penetration) monopoly power vis-à-vis its (their) competitors. In a circularly homeopolistic industry an independent price-cut by a firm would constitute *use* of its (penetration) monopoly power vis-à-vis its competitors. If, on the other hand, firms in a circularly homeopolistic industry agreed *not* to use their (penetration) monopoly power vis-à-vis one another they could be held as violators of section 1 of the Sherman Act, in so far as such an agreement is tantamount to an agreement not to compete in the price dimension. This peculiarity of the Sherman Act is brought out forcefully, I believe, when we employ the concept of "penetration" as defined in this paper.

STABILIZING RESIDENTIAL CONSTRUCTION—A REVIEW OF THE POSTWAR TEST

By LEO GREBLER*

I

Stabilization of construction activity, as a means of cushioning general business fluctuations, received considerable attention both before and during the war. The limitations of stabilization policies operating through a single, though major activity, such as construction, were more and more recognized, but it was widely believed that greater stability in the volume of construction itself would be a worthwhile objective. The two types of construction in which government action toward greater stability was held to be most promising were public construction and residential building.

The opportunities for government action were obvious so far as public construction was concerned, although there were differences of opinion over the magnitude of these opportunities and the possibility of coordinated measures by the numerous federal, state, and local government bodies. The inclusion of residential building in proposed stabilization policies rested principally on two grounds: (1) Stability of public construction alone, even if it were possible, could not be expected to maintain a reasonably stable volume of total new construction, and (2) The federal government could exert considerable influence on the volume and direction of residential building through the various financial aids which were developed during the 'thirties.

This writer some time ago suggested a framework for a federal housing policy that was designed to mitigate the pronounced cyclical fluctuations in residential construction activity. The proposed means were withdrawal or reduction, during periods of high demand for dwellings, of federal financial aids, and return or intensification of these aids during periods of low demand for dwellings. In detail, the proposal contemplated variations in downpayment requirements, maximum amortization periods, and maximum interest rates for mortgage loans accepted for insurance by the Federal Housing Administration; synchronized credit policies of the Federal Home Loan Banks in extending loans to its member institutions which are primary mort-

* The author is research professor, Institute for Urban Land Use and Housing Studies, Columbia University.

gage lenders; and variations in the volume of such federally aided public housing programs as may be approved by the Congress as a matter of long-range housing policy.¹ As one of several supplemental policies it was recommended that the Federal Housing Administration during booms refuse to recognize excessive building costs in its appraisals, which would automatically lower the ratio of loan to purchase price and would therefore be tantamount to requiring larger downpayments. These suggestions were later broadened to include steps toward greater stability in the volume of public construction, through different means.²

It was made clear that the proposals did not contemplate "a rigid maintenance at all times of a predetermined volume of construction" and that they could be adapted to changing business conditions. One of the purposes of the suggested policies was "to break the over-extended cost-price structure that characterizes building booms," by withholding public construction and by tightening of credit terms for private housing during boom periods.

II

The course of government housing policies from VJ-day to the end of 1948 furnishes an instructive record in respect to these and similar proposals. The postwar experience now covers a sufficiently long period to permit at least some preliminary conclusions. While legislation in the early phase of this period proceeded in the twilight of doubt over the prevalence of inflationary or deflationary forces in the transition from war to peace, the preponderance of inflationary tendencies was apparent during at least three-fourths of the time elapsed from VJ-day to the close of last year.

The preliminary conclusions of this review are disappointing for those who expected that the greatly increased responsibilities of the federal government for economic stability, and the government's direct fiscal interest through its heavy commitments and involvements in the housing market, would stimulate the adoption of policies designed to mitigate fluctuations in this segment of the economy. In summary, the first acid test for the adoption of such policies has been negative. Legislative actions since VJ-day have been designed to enlarge the effective demand for new housing through cheap credit and similar devices. These actions were taken at a time when the demand already exceeded the supply of new dwellings which was limited by materials

¹ "Housing Policy and the Building Cycle," Rev. Econ. Statistics, Vol. XXIV, No. 2 (May, 1942), pp. 66-74.

² *Stabilization of Construction Employment—A Step toward Over-All Stabilization*, in The Winning Plans in the Pabst Postwar Employment Awards (Pabst Brewing Company, Milwaukee, Wis., 1944).

and labor resources, with effects that have contributed to instability. The trend becomes evident from a brief review of recent legislation:

1. The Servicemen's Readjustment Act of *June 1944* provided for the guarantee by the Veterans Administration of G.I. home loans covering up to 100 per cent of the "reasonable normal value" of the property. Thus, the concept of low downpayments developed in the FHA mortgage insurance system before and during the war was stretched further to the extreme of no downpayment loans. The guarantee was for 50 per cent of the mortgage principal but could not exceed \$2000.

2. An amendment to this act in *December 1945* increased the maximum amount of guarantee from \$2000 to \$4000 and changed the basis of appraisal from "reasonable *normal* value" (italics supplied) to "reasonable value." Thus, valuations under this program were loosened rather than tightened.

3. The wartime Title VI of the National Housing Act, which allowed much more liberal FHA financing of new housing for war workers than was possible under the peacetime FHA program, and which had become inactive in the Fall of 1945, was re-enacted in *May 1946* for veterans' housing. At the same time, various provisions of the act were further liberalized. The basis for determining the loan amount was changed from the customary "value" concept to that of "necessary current cost." The maximum loan amount for single-family dwellings was raised from \$5400 to \$8100, with similar adjustments for other types of dwellings. Title VI was allowed to expire on April 30, 1948, but was again revived for rental housing in August of that year.

4. The Housing Act of *1948*, which represents essentially the much debated Taft-Ellender-Wagner General Housing Bill minus public housing and urban redevelopment, contained the following provisions for stimulation of housing construction:

(a) Special FHA insurance aids and RFC loans for prefabricated and other mass-produced housing;

(b) 90- to 95-per cent insured loans for small new houses with amortization up to 30 years and other liberalizations of the prewar terms for FHA home financing, which in effect tend to offset the withdrawal of cheap home-financing credit under Title VI;

(c) 90-per cent FHA insured loans for rental housing and 95-per cent loans for cooperative veterans' housing;

(d) Authority of the Federal National Mortgage Association to purchase certain FHA and veterans' home loans, up to 50 per cent of the total loans of this type originated by a lender, virtually permitting lenders to make these loans and turn them over to a government-owned holder;

(e) FHA insurance of investments in certain types of rental housing (so-called yield insurance).

The emphasis in public discussion on the exclusion of federal aids for public housing and urban redevelopment has obscured the significance of the federal financial aids which are incorporated in this act. The only recognition in the act of possible inflationary influences is expressed in a slight tightening of the appraisal basis for rental housing projects under Title VI of the National Housing Act, and in the authorization to increase the maximum interest rate for veterans' home loans from 4 per cent to $4\frac{1}{2}$ per cent (which at the time of this writing had not been used).

This sketchy summary deals only with major financial aids. It omits non-financial aspects of the Veterans Emergency Housing Program which was in effective operation roughly one year, from the Spring of 1946 through the Spring of 1947, and which contained a great many unstabilizing elements. One of these was the program target itself of 2,700,000 housing units within two years, which was utterly unrealistic in terms of prospective materials and labor availability unless one assumed the presence of large, idle (and transferable) resources, a condition which actually did not obtain. The high target and the attendant drive caused a large initial volume of starts of housing units, the completion of which was delayed. The resulting pressure added to the upward movement of costs and prices. The control and priority features of the program failed to perform the intended function of giving housing a prior claim on economic resources, as this writer sees it, primarily for these reasons: (1) The program itself did not recognize the breadth and depth of controls that were necessary for its accomplishment in an atmosphere of fairly general overemployment, and (2) The community-at-large was unwilling to forego other things in favor of housing to anywhere near the extent to which it was willing to forego other things in favor of waging war.³

III

On the whole, it is only fair to say that federal credit policy in respect to housing since VJ-day represents an extension and intensification of devices which originated during the depression and were judged to have had a degree of success in restoring the badly shattered real-estate and mortgage markets and in stimulating new residential construction. This experience was broadly projected into the postwar period, only that stronger and stronger doses of the same medicine were administered. There has been little recognition in federal policy of the fundamental difference in the effects of liberal credit during

³ For a more extensive though preliminary appraisal of the Veterans Emergency Housing Program, see Coleman Woodbury's paper before the 59th Annual Meeting of the American Economic Association, *Papers and Proceedings*, *Am. Econ. Rev.*, Vol. XXXVII, No. 2 (May, 1947), p. 508. The present article deals only with the trends and implications of federal financial policies in respect to residential building.

periods of substantial underutilization of resources and during periods of full employment or overemployment of resources. During the 'thirties, of course, it was possible through liberal credit to stimulate the demand for housing without substantial rise in the cost of, and the price for, new dwellings. The large unused resources for construction could be brought back into employment without bidding up wages and materials prices. Moreover, the market for existing houses was a buyers' market in most areas and localities, and the large number of such houses offered for sale at distress or near-distress prices served as a check on prices for new dwellings. When the volume of new construction is limited by materials and labor supply and a sellers' market prevails for existing houses, as was the case from VJ-day to late in 1948, liberal credit is likely to push up costs and prices rather than to increase production, *i.e.*, to be inflationary.⁴

The processes through which these effects come into operation need not be explained to an audience of economists, but they require a great deal of explanation for legislators, administrators, and the public at large.⁵ And even when they are adequately explained, one cannot be too certain that policy will be guided by considerations that necessarily place more emphasis on the long run than on the short run. If it is correct to assume that stabilization measures must include restraints during booms, they are apt, by their very nature, to hurt or inconvenience people or groups of people.

This was recognized in earlier proposals to restrain housing credit during periods of high demand. "... Problems of a political nature may arise in the execution of such a policy. Liberalization of mortgage credit terms has found general approval on the part of Congress, the home-buying public, and builders. The same quarters may bring pressure to bear against any tightening of credit terms on the upgrade of the cycle."⁶ But the full force of political and social pressures was perhaps not adequately appraised. Federal housing policies since VJ-day were shaped almost exclusively in terms of relieving the housing shortage by maximum stimulation of new construction, and by

⁴ It may be noted in passing that a public housing program would have had similar effects during the period under consideration. Public housing through 1948 was limited to a federal program of temporary veterans' housing including the relocation and reuse of existing temporary structures, and to a substantial volume of public construction in New York City. Other state and local programs were insignificant. The major program of permanent public housing adopted by the Congress in the summer of 1949 is not within the purview of this article which considers housing policies in the light of business conditions prevailing to the end of last year.

⁵ For a lucid statement of these processes, see Ernest M. Fisher, "The Role of Credit in the Real Estate Market," address before the 41st Annual Meeting of the American Life Convention in Chicago, October 7-11, 1946.

⁶ *Housing Policy and the Building Cycle*, p. 72.

the problems of housing for veterans. Policies of restraint would at least have appeared to compromise the objective of speedy provision of housing for veterans and of rapid removal of the shortage. The fact that veterans generally are lower in the income scale than non-veterans gave further impetus to liberalization of credit. Withdrawal of federal credit aids, once they were on the statute books, was handicapped both by political implications and by apprehension that such action would be more than corrective, *i.e.*, produce a sharp decline in the volume of construction.

While admitting the existence of powerful non-economic forces in shaping policy, the economist may well undertake to probe the means employed toward the attainment of purported ends. In this connection, it is worth while to examine broad relationships between liberal credit and the two principal objectives of federal housing policies since VJ-day: maximum increase in housing supply, and "channeling" of new housing into those family income groups which are considered to need it most. As to maximum increase in housing supply, the argument for liberal credit usually revolves around the point that a high rate of new construction is the only effective means of combating inflation in the housing market, and that liberal credit to accelerate the rate of construction is therefore anti-inflationary and stabilizing in effect. Housing represents, of course, the extreme case of durable goods where the strain on resources for a given increase in production is out of proportion to the immediate increase in total supply. Thus, an effort under full employment to raise the output of nonfarm dwellings during one year by 300,000 units, or roughly one-third the actual annual production in 1947 and 1948, would involve command over one-third more materials and labor resources (in the absence of technological miracles). Such an effort, if successful, must have a wholly disruptive effect on resource prices not only for the increment of 300,000 units but for all new units. Yet, it would increase the total supply of nonfarm housing by less than 1 per cent (on the basis of roughly 34 million nonfarm dwelling units standing in April 1947, according to the Bureau of the Census). The anti-inflationary effects of maximizing the rate of new construction and adding to the housing supply are extremely small and slow. The inflationary effects of liberal credit for maximization of new building are large and immediate, and yet lasting since they become embedded in long-term mortgage obligations.⁷

⁷ The argument could be extended to alternatives of maximum output as a means of supplying housing for those not in possession of housing units. This would, however, involve the examination of rent control and its effects on both housing supply and housing demand. We are here concerned only with those principles that would apply under any circumstances during a period of full employment.

As to "channeling" new housing into middle- and lower-income groups, the argument for liberal credit rests on misunderstood implications of plain arithmetic. The arithmetic is simple enough: For example, the level monthly payment on a \$1000 loan for 15 years at 5 per cent interest is \$7.91 but is reduced to \$6.33 when the terms are liberalized to 20 years and $4\frac{1}{2}$ per cent, and to \$5.28 when the terms are further liberalized to 25 years and 4 per cent. Therefore, it is concluded that liberalization of terms, particularly if limited to certain groups of the population and to new dwellings within certain broadly defined price or rent brackets, will bring new housing within the reach of consumers who otherwise could not afford it. This is, of course, patently wrong when at the same time the maximum loan-to-value ratio is increased, say, from 80 to 90 or 100 per cent, for this augments the amount of loan. In any event, the simple arithmetic assumes that loan amounts and prices are constant and remain unaffected by more liberal credit.

Actually, in a sellers' market, the more generous credit terms are capitalized into higher prices and larger loan amounts, which tend to nullify the benefits of lower interest rates, longer amortization periods, and lower or no-downpayment requirements. As a result, the moderate income groups for which the benefits were designed soon find themselves approximately where they were before, or in a worse position if the magnification effects of expectations on prices are considered. The forces producing this result cannot be measured precisely with now available tools of analysis, but their operation is illustrated by the fact that a 20-per cent increase in the price of houses and a corresponding increase in loan amount are sufficient to wipe out all of the benefits from a change in loan terms from $4\frac{1}{2}$ per cent interest, 20 years, to 4 per cent, 25 years.

It is probable that credit aids in the first instance enabled more veterans to buy houses than would have been the case otherwise, or to buy them earlier. However, when the inflationary effects of the credit aids began to cumulate, the price rise eliminated an increasing number of marginal veteran-buyers, as is suggested by the sharp drop in veteran home loans since early in 1948, both in absolute number and in proportion to all home mortgage loans.

The magnitude of the inflationary effects of federal housing credit policies cannot be established in any conclusive fashion. Results of liberal credit cannot be dissociated from other factors that were at work simultaneously and created upward pressures on construction costs and even more on prices for the finished products. It is only fair to say that postwar conditions were conducive to unconservative lending practices even if such practices had not been sanctioned and

supported by the federal government. All that can be done is to show some quantitative relationships. Thus, in the neighborhood of 50 per cent of all new nonfarm dwelling units were financed by FHA and VA loans in both 1947 and 1948. The largest comparable proportion before the war was 35 per cent, and the 1945 proportion was 20 per cent. In the past two years, more than a quarter of the total number of nonfarm mortgages recorded (of \$20,000 or less) were either FHA or VA loans, and they represented over 35 per cent of the total amount recorded. The comparable prewar proportion was about 12 per cent of the number and 20 per cent of the amount of mortgages recorded. The mortgage debt on 1- to 4-family nonfarm houses increased from less than \$20 billion at the end of 1945 to \$24.4 billion in 1946, approximately \$30 billion in 1947, and probably \$35 billion in 1948. Government-insured or -guaranteed loans now probably account for about one-third of this debt. In contrast, government-insured (FHA) loans represented little over 9 per cent of the debt in 1939.

It seems reasonable to infer from these data that the availability of government insurance or guarantee has had significant effects in expanding the supply of mortgage funds for the financing both of new construction and transfers of existing housing.

IV

It might perhaps be questioned that the experience since VJ-day represents a fair test of the political and social difficulties that beset a policy designed to bring greater stability to residential construction. The test has been limited to a postwar period in which a severe housing shortage and the problem of providing housing for veterans created unusual pressures. Could stabilization policies be more successful in different circumstances?

The postwar test has undoubtedly been conducted under adverse circumstances and may therefore be considered a most severe one. However, the annals of building booms show that they occur characteristically after wars. More importantly, the phenomena and forces creating a postwar housing boom are essentially the same as those creating any housing boom, except that they appear perhaps in more concentrated form. Housing booms are typically preceded by housing shortages involving hardships and pressures. Thus, as housing is increasingly clothed with public interest, there is real danger that the existence of a shortage will always tend to generate government actions of the same kind as were observed during this postwar period—actions which are likely to accentuate rather than mitigate fluctuations in the volume of residential construction. Consequently, the fact that housing has become a matter of national concern, and that residential

building is subject to strong governmental influences, may make government policies directed toward greater stability more rather than less difficult.⁸ This danger will exist so long as the role of credit is not more clearly and generally understood, and so long as the conflict between the social objectives of economic stability and of rapid removal of the housing shortage (or rapid improvement of housing conditions) is not squarely faced. This conflict is a real one in a period of full employment when housing production cannot be maximized without sacrifice of economic stability, and when economic stability cannot be maintained without sacrifice of maximum housing construction.

But granted that liberalization of credit to speed new housing construction accentuates the boom, must this necessarily have an unstabilizing effect? In this field as well as others, stabilization proposals which include both restraining measures operating on the upgrade of the cycle and stimulating measures operating on the downgrade of the cycle have been met with the dictum that "there is nothing wrong with the boom." The objective of stabilization policies, in this view, should be the continuance of activity at boom levels.

The experience since VJ-day in housing construction as well as other lines has been a rather effective demonstration of the characteristics of booms, to which aggregative economics has paid scant attention. Only a few aspects will be mentioned such as the series of materials and labor bottlenecks that have plagued residential as well as other types of construction; apparent low efficiency of both labor and management; continuous upward pressures on costs and prices; disproportionate price increases for different resources; disruption and corruption of distribution exemplified by "gray markets"; a tendency toward low quality fostered by materials substitutions, poor workmanship, and emphasis on speed and easy profits characteristic of a

⁸ The following passage from Roy Harrod's critique of recent British government policies may be noted in this connection: "One of the more sophisticated arguments, but a powerful one, in favour of the nationalisation or State control of certain industries is that the State will succeed in achieving a steadier flow of capital outlay in those industries, through good years and bad, than private enterprise, influenced as that has always been by the vagaries of the trade cycle. In this regard, then, it was claimed that the State should and would do better than private enterprise. As things are turning out, it is doing much worse. This is pre-eminently a time when private enterprise would tend to be induced, under the influence of the hyper-boom conditions that prevail, to go forward too hastily with its capital extensions. It was urged that the wise State, once in control of these enterprises, would go slower during the boom, despite the *prima facie* case for expansion, and speed up capital outlay during a depression, even when there was not an immediate financial case for doing so. In fact the State has indulged in greater excesses in this boom than private enterprise ever would. Its whole influence has been to increase rather than to damp down the tempo." *Are These Hardships Necessary?* (London, 1947), pp. 64-65.

sellers' market; long-term commitments by house purchasers and rental housing investors based on the most optimistic expectations. Since this is elementary, a reminder may suffice that maintenance of boom levels of activity entails the danger of maintaining imbalances such as these. The most serious among them is perhaps the tendency of construction costs and prices to rise more than other prices, and more than disposable income of large segments of the population. This tendency causes concern in view of the one fact on which practically all housing analysts seem to agree, *e.g.*, that cost is at the heart of the housing problem.

The imbalances of the boom result, of course, from efforts in the market place or in government to push output beyond the limits of capacity which has little short-term flexibility, especially during periods of generally full employment. A greater clarification seems to be needed of the relationship between output stabilization and capacity. A feasible objective of stabilization policies may perhaps be the maintenance of production at a level close to, but not exceeding, capacity.

It is possible to interpret recent federal housing policies as part and parcel of a long-term effort to devote a larger proportion of total resources to residential construction, which would require a continuous expansion of capacity over a considerable period of time. In this case, increasing relative costs might be considered the price paid for re-allocation of resources. To the extent that consumers were unwilling or unable to cause the resource shift, the government would pay the price in terms of subsidies or losses on loans, and there would be little if any concern over imbalances produced in the process. If this interpretation is correct, the consequences of pursuing such a policy under conditions of full or nearly full employment must be clearly recognized. One of the consequences would be a snowballing of federal credit and subsidy aids as an increasingly large proportion of families would be unable to stay in the race between rising relative costs and prices and their ability to pay. Another likely consequence would be an increase in the relative cost of all types of construction, both private and public, since housing and other types of construction draw largely on the same materials and labor resources. In addition, government insurance of liberal home mortgage loans or direct government loans would seem to be an extremely poor means of executing such a resource shift. For these loans represent long-term obligations of millions of citizens, a large number of whom might have the notion of making strenuous efforts at repayment rather than "walk out" on the government when obligations become too burdensome. It is hardly a defensible public policy to favor cynical over honest borrowers.

V

It remains to consider briefly some of the implications of the federal housing policies during the past three years. So far, some of the financial (as well as other) aspects of the postwar housing boom have shown an amazing degree of resemblance to those of the boom after World War I—and an alarming one in view of the permanent improvements in mortgage lending practices and policies that were expected to result from the new federal instrumentalities such as the Home Loan Bank Board and the Federal Housing Administration. Shoestring financing in the production of housing and in the purchase of houses for owner-occupancy is probably as widespread as during the earlier period. That the combination of junior and first loans during the 'twenties has been replaced largely by government-guaranteed or -insured first mortgages covering 80 to 100 per cent of appraised value is a superficial difference, except that the high-percentage first mortgages of today are for long terms and provide for regular amortization, whereas the junior loans of the 'twenties were for short or medium terms. Moreover, the use of second mortgages which had been reduced sharply during the 'thirties appears to have increased substantially, although there are no statistical data to evidence this trend. Whether appraisal and underwriting procedures generally are any sounder than during the 'twenties is an open question, despite the addition of many "scientific" trappings to appraisal techniques.

Likewise, it is impossible, in the absence of sufficient data, to generalize on the question whether house purchasers during recent years have overcommitted themselves in the same degree that was observed during the boom of the 'twenties. The more general use of mortgage loans providing for regular amortization is probably the one feature which distinguishes recent mortgage lending from that of earlier periods; but it remains to be seen whether it will be a saving feature, since amortization of the now customary loans with long maturities is slow during the first few years. The fact that such a large proportion of mortgage loans outstanding is insured or guaranteed by the federal government will probably cushion the effect of untoward developments on financial institutions, but whether it will reduce the impact of such developments on the financial system as a whole remains an open question.

Some correction of lending practices characteristic of the immediate postwar period could be observed in late 1947 and in 1948 when mortgagees unquestionably developed a tendency toward greater caution and selectivity. A substantial proportion of government-guaranteed and -insured loans was written for shorter maturities and on lower loan-to-value ratios than the statutory maxima would suggest, and

loan rejections were on the increase. But this development was immediately interpreted by legislators and administrators as representing a shortage of mortgage funds and led to new government programs such as the secondary market operation of the Federal National Mortgage Association authorized in the Housing Act of 1948. In other words, such corrective market forces as have come into operation were weakened by government action pulling the other way, but the final result of the conflict between restraining market forces and stimulating government programs is still in the balance.

Thus, it would be premature to express any summary judgment as to whether recent financing practices fostered by government policies, if continued, will in the end necessarily produce a collapse of the kind and magnitude experienced after the boom of the 'twenties—in spite of uncomfortable parallels that could be observed. The outcome will, of course, be affected by many things other than those reviewed in this article. All that can be said with a degree of confidence is that recent governmental policies have done nothing to prevent fluctuations as great as, or even greater than, those observed in previous periods. They have certainly contributed to the sharp increase in building costs and in prices of new as well as existing houses.

Another implication is the kind of stabilizing government action that is left for application during periods of serious decline in the volume of residential construction. A great deal of the ammunition in the arsenal of government has already been shot away in the recent post-war boom, and will be shot away under the Housing Act of 1948. After supporting 80 to 100 per cent loans for housing during a period of full employment, at unprecedentedly low interest rates and for terms of 25 years or even more, what weapons are left to stimulate housing construction when a stimulus is warranted?

It appears that a program of cheap credit within the framework of private financial institutions could not be carried any further than it has been carried to date. Obviously, the guarantee of loans of more than 100 per cent of appraisal value or cost would be an absurdity and tantamount to a premium for builders and for purchasers.⁹ The effects of further extensions of amortization periods would be less and less significant so far as total financial charges are concerned. Further reductions in mortgage interest rates would depend upon general money market conditions and the not yet fully tested ability of the monetary authorities to manipulate rates. The limits to continued reductions of mortgage interest rates were highlighted in late 1947 and 1948 when even a slight increase in general interest rate levels dimin-

⁹ It may be noted that 90-per cent loans normally enable a builder to cover all of his out-of-pocket expenses or, in the lingo of the trade, to "mortgage out."

ished or wiped out the net-yield margin in favor of 4-per cent guaranteed home mortgage loans, and led to a diminishing supply of mortgage funds *at that rate*. Thus, the principal remaining weapons for future stimulation of residential building activity would seem to be (1) large-scale substitution of direct and probably not self-liquidating government credit for private credit, and (2) a large-scale program of subsidized public housing.

These measures, however, would come into operation at a much higher level of building costs caused by the government aids which were extended during the boom and would, in fact, tend to underpin that level of costs. They would, therefore, either not go as far as they might otherwise, or they would require much greater outlays and burdens than would be the case otherwise. In addition, there would be a profound change in the institutional framework of the American economy if direct government credit and subsidies were to become the principal supports of a high level of residential construction. These prospects may appear either gloomy or bright, depending upon viewpoints. But they must be evaluated against the alternative of more flexible policies in respect to credit and subsidies for housing, geared to minimizing output and employment fluctuations.

THE DYNAMICS OF PRICE FLEXIBILITY

By THOMAS C. SCHELLING*

I. Introduction

The purely theoretical case against price flexibility, as a device for restoring or assuring full employment, has recently come to hinge on dynamic considerations, specifically on the speculative reaction to price changes. Mr. Don Patinkin and Mr. Lawrence Klein have both stated this position.¹ They argue that, while there may at any moment be a price *level* which, if sustained, would yield full employment, the movement of prices toward that level would set off adverse reactions which would dominate the system, causing an aggravation rather than amelioration of unemployment.

It is the purpose of this paper to point out an incompleteness in their logic and to develop an explicit analysis of the dynamic problem involved. First we shall summarize briefly the argument of Mr. Patinkin and Mr. Klein and suggest wherein their omission lies; then we shall present a diagrammatic analysis of the subject.

Briefly Mr. Patinkin's argument is this. A fall in the general price level raises the real value of net cash assets.² The impulse to save is negatively related to the real value of net assets. A fall in general price level consequently lowers the savings function; a rise in price level raises it. There is some price level at which the savings function has the same value at full employment as the investment function.³ Furthermore this "full employment" price level represents, in a certain sense, a stable equilibrium: if prices are too high, employment is less than full,

* The author is currently economic analyst with the Economic Cooperation Administration Mission to Denmark, on leave from Harvard University.

¹ Don Patinkin, "Price Flexibility and Full Employment," *Am. Econ. Rev.*, Vol. XXXVIII No. 4 (Sept., 1948), pp. 543-64. Lawrence Klein, *The Keynesian Revolution* (New York Macmillan, 1947), pp. 88, 89, 109.

² See Mr. Patinkin's discussion of what constitutes "net cash assets" for this purpose *op. cit.*, pp. 549-51. The problem of definition is based on the fact that many cash assets *e.g.*, most demand deposits, are offset by cash liabilities of others. Unless there are asymmetries of response, only certain government liabilities and the monetary gold stock may be included. Mr. Patinkin would include interest-bearing government securities held by the public; this inclusion is correct only if potential taxpayers fail to recognize an increase in the real value of discounted future tax liabilities—which they probably fail to do by and large, at least to a completely offsetting extent.

³ Mr. Patinkin recognizes that the price level effect may be asymptotic.

prices fall; if prices are too low, employment is overfull, prices rise.⁴ Mr. Klein outlines a similar case, although his orientation is principally toward the effect of larger real cash balances on the interest rate, hence on investment (and consumption, if one wishes).

To this line of reasoning Mr. Patinkin then raises two objections, a policy objection and a theoretical objection; Mr. Klein raises the same theoretical objection.⁵ The policy objection is that the adjustment may take too long; wages and prices fall at some finite rate, perhaps the rate is slow and the required fall is great and many months or years are required to lift the real value of net cash assets to the full employment level. The theoretical argument is that the static hypotheses fail to represent all the essential parts of the economic system; expectations have been left out. For when expectations are admitted, it follows that the price changes may cause anticipations of further price changes which affect the level of employment in the opposite direction. When prices fall, and further decline is expected, consumers postpone purchases, businesses liquidate inventory and defer construction, etc. Consequently, while there exists some price level consistent with full employment, the adverse effects of price changes toward that level dominate, and "it is impossible to reach (or, having reached, remain at) such a position."⁶

The above argument may be attacked in either of two ways. One would be to deny the quantitative implications of it: the speculative effect *might* be small, the price level effect *might* be substantial. This becomes an empirical argument, and we shall not pursue it here. The other attack is to grant the essential mechanics of the thing, and proceed to trace the ultimate outcome.

First, it will probably be agreed that, in combatting unemployment, what we are trying to minimize is some function of the whole time pattern of unemployment. A brief period of severe unemployment will perhaps be considered less undesirable than some longer period of mild unemployment.

Second, price flexibility—or wage flexibility, since we shall assume close correspondence between wages and prices—means that when unemployment exists, wages and prices fall at some finite rate over time. (Instantaneous adjustment is not only empirically implausible but precludes the whole question of stability.) Furthermore, the rate of wage-price decline may be geared to the amount of unemployment. It may, in fact, be a rather complicated function of present and past unemployment, *i.e.*, duration may have some effect on the rate of price-

⁴ We shall allow the process to work on both sides of full employment.

⁵ Klein, *The Keynesian Revolution*, pp. 88, 89, 109.

⁶ Patinkin, *op. cit.*, p. 559.

wage decline; but we shall assume that the time rate of change of wages and prices depends on the amount of unemployment.

The crux of our argument is this: the speculative expectation effect *may*, by initially increasing unemployment, accelerate the price decline and ultimately shorten the duration of unemployment. Essential to this result are two conditions: (1) that, after some lapse of time, the price *level* effect asserts itself over the anticipation effect, and (2) that the resulting time pattern of unemployment actually does, according to somebody's criterion, represent an improvement over the alternative, slower, direct approach to full employment, *i.e.*, the one which would occur in the absence of the "adverse" speculative reaction.

What we are talking about is a "cold turkey" remedy, in contrast to a tapering off. It is as though the best way to cure a cold were to make it initially worse so that the patient would go to bed and take care of himself.

It is difficult intuitively to see whether there is a flaw or hidden inconsistency in this argument. One might suspect that the mechanism works only if "peculiar" shapes are imputed to the relevant behavior functions. Fortunately, the whole analysis can be put into a diagram which, in spite of some multiplicity of variables, is fairly simple.

In the abstract, the problem to be studied is that of one variable whose rate of change over time is related to a second variable whose value in turn is related both to the value of the first and to the latter's rate of change over time. While the following analysis will proceed in terms of the present question of price flexibility, problems of this form may be found in other contexts.⁷

II. Analysis

First we must specify what our behavior functions are and formulate the concepts of adjustment and stability. We have two behavior equations in this model; they are all we need for the case being analyzed. One is this: the rate of wage-price decline depends on the amount of unemployment; specifically, the greater the unemployment, the faster the fall of wages and prices. Denoting unemployment by U , and the rate of price-wage decline by P' , we draw the curve labelled $P'(U)$ in the diagram to represent this relationship between the rate of price decline and the amount of unemployment. The horizontal axis (Figure 1) measures unemployment; the vertical axis, labelled P' , measures the rate of price decline in, say, per cent per month.

The second hypothesis is this: the level of unemployment depends on both the price level and the rate of price change. (We have implicitly, of course, an investment and a consumption—or savings—function.

⁷ See the final paragraphs of this paper for two examples.

We may, to fix ideas, think of the absolute price level as determining the height of the savings function, and the rate of price change as determining the height of the investment function.) While income, or employment, depends only on price, it depends on two aspects of price: the level itself and its rate of change. We treat these as two separate variables (as far as the unemployment function is concerned). The two variables, P and P' , are completely related in that, knowing the course of P over time the course of P' can be derived; and, given the

FIGURE 1

course of P' over time and the initial value of P , the entire course of P can be constructed. It is as though some magnitude depended on both the speed and distance of a moving object, where the speed is, of course, the rate of change of the object's distance over time.

These two behavior functions would be sufficient to determine the course of the variables over time. If both of these functions are satisfied, *i.e.*, if the values of U , P , and P' conform to our hypotheses, the time path of U and the time path of P (hence also of P') can be traced if we know the shapes of the functions. We might be tempted at this

point to assume certain shapes for our behavior functions and trace out the time pattern implied in them, to see whether unemployment tended toward zero and price toward some equilibrium value. But this procedure would avoid the main problem, namely whether our two functions necessarily are, or can be, simultaneously satisfied. For in reality we are dealing here with two levels, or orders, of equilibrium: equilibrium in the sense of satisfaction of our two behavior functions—a dynamic equilibrium in which the variables are in motion—and “full employment equilibrium”—a static equilibrium whose condition is that P , U , and P' have certain values, namely zero for U and P' . We must first ascertain whether our two behavior functions enjoy dynamic stability, before analyzing the implications of their simultaneous satisfaction.

We must look now at the concept of dynamic stability. Two or more behavior patterns (or functions, or equations) are considered stable if, when an initial set of actual values differs from those which satisfy the functions, the values of the variables ultimately approach those values which do satisfy them, these latter values being referred to as “solution values” or “equilibrium values.” Inherent in this concept is the recognition that divergencies from equilibrium may occur, that the variables do not adjust instantaneously to their function values, *i.e.*, that the behavior patterns represent tendencies, propensities, or aggregates of individual intentions.⁸ The solution of the behavior equations is significant only if (1) there actually is a solution—there is nothing sociologically necessary about the existence of a solution, *i.e.*, about the consistency of all economic intentions, and (2) the solution is stable as defined above. If the solution is not stable, the implications of simultaneous solution are largely irrelevant.

It is analytically useful—and frequently plausible empirically—to assume that one type of behavior adjustment is more rapid than the other, even instantaneously rapid by comparison. For example, in the cobweb analysis demand is usually assumed to adjust immediately to price, while supply responds slowly or with a lag. According to this point of view, one of the functions is considered to be always satisfied; *e.g.*, price-quantity combinations always satisfy the demand function in the usual cobweb analysis. Often, for purposes of analysis, it does not matter which variable is taken as adjusting instantaneously and which as the slow one whose behavior pattern is never satisfied until equi-

⁸ That is, each function is itself one (short-run) equilibrium condition. The full interpretation of $U = f(P, P')$ is that:

$$\frac{dU}{dt} = \Phi [U - f(P, P')], \text{ where } \Phi [0] = 0$$

and $\text{Sign } \Phi [U - f(P, P')] = \text{minus Sign } [U - f(P, P')]$.

librium is reached. (In the present case this is so; in the cobweb case the stability conclusions are reversed.) Intermediate positions seem more realistic, in which rates of adjustment of both variables are explicitly considered, and neither function is quite satisfied until equilibrium is reached. Diagrammatic analysis is much simpler if we let one variable adjust rapidly in relation to the other; the reader can reverse or compromise this position in the analysis below, and convince himself that the conclusions remain valid.

Of the two functions, we shall consider the price-flexibility function as the rapidly adjusting one, *i.e.*, the function relating the rate of price-wage decline to the amount of unemployment, the one labelled $P'(U)$. We assume, that is, that the rate of price-wage decline is always exactly geared to the amount of unemployment, in accordance with this function, with no appreciable lag. (Which is to say that it adjusts so quickly that no appreciable change occurs in either U or P while the adjustment takes place.) And we assume that unemployment adjusts at a slower rate, always moving *in the direction of* its value according to the unemployment function (which is a function of both P and P').

We proceed now to the first diagram. The $P'(U)$ function, relating the rate of wage-price decline to unemployment, is given an ogive shape, to indicate that price-wage rates fall slowly at low levels of unemployment, that the rate of price-cutting sharply rises beyond some critical unemployment level, and that it then tapers off to perhaps an asymptote. We give it this shape only to demonstrate the possibility of certain results, and not because of its compelling plausibility. This function goes through the origin, which only means that our definition of "price flexibility" is consistent with our definition of "full employment." It rises steadily to the right, and it appears in both the north-east and the south-west quadrant, those of unemployment and over-employment respectively, being negative (rising prices) in the over-employment range.

We next draw our unemployment function. Since our diagram is two-dimensional, we cannot show U as function both of P and of P' . So we draw the U function corresponding to a given value of P , namely P_1 , labelling this function $U(P', P_1)$. This function rises to the right; it is drawn as a straight line for manipulative simplicity. If it were vertical, it would indicate the absence of the expectation effect; the less steeply it is sloped, the greater is the indicated sensitivity to price-change. Since the U function corresponding to P_1 cuts the horizontal axis to the right of the origin, we know that P_1 is greater than P_0 , the full employment equilibrium price level, *i.e.*, the price level which, if sustained, would be associated with full employment. That is, the particular function drawn for P_1 shows positive unemployment for zero rate of price change.

We assume now that price P_1 exists, and that unemployment is of the amount denoted by x_1 on the diagram. (We have thus subjected our system to two disturbances from full equilibrium, one shifting the U function at current prices so that price is above equilibrium price, and another knocking unemployment out of line with the unemployment function.) Immediately prices begin to fall at the rate given by the P' function, namely the rate r on the diagram.

With the given price, P_1 , falling at the rate r , unemployment tends to move toward x_2 , the function value for U corresponding to P_1 and r . This movement takes a finite length of time, during which (1) the rate of price decline increases in accordance with the P' function, and (2) price itself is declining. So the path traced out by U and P' is along the P' function, toward the receding value of the U function. If the adjustment of U is fast relative to P' (not relative to the adjustment speed of P' , which would be P'' , but to the rate of change of price itself) multiplied by the derivative of U with respect to P ; *i.e.*, if the adjustment speed of U is fast relative to the *shift* of the $U(P')$ function as P changes; the "final" position is near x_3 with P' equal to the P' function value corresponding to x_3 . But, if the price changes during the adjustment have shifted the U function appreciably, then the U function has been moving appreciably leftwards as U increased (for the falling price means a falling savings function and a falling unemployment function) and the end result is at, say, y_1 , with price P_2 , and price now changing at the rate q .

But this "end result" is only the very short-run solution; for price is changing according to the P' function, and the U function is therefore moving steadily leftwards. So y_1 , q , and P_2 only represent points on a moving equilibrium; P_2 is not, except by coincidence, equal to P_0 .⁹

Before taking the next step, we should notice that our intersection of the U and P' functions is stable as we have drawn it; *i.e.*, an initial value of U off the U function approaches its function value (ultimately approaches it: the solution value may move ahead of U itself for some distance faster than U moves.) This is dynamic stability—of our behavior functions, not yet of the P_0 price-full employment equilibrium, although that will be seen later to follow. Had the U curve intersected the P' curve from above, the behavior system would have been unstable (at least until another intersection were approached) and U would either rise or fall without approaching any limiting value.

It will be noticed that the expectation effect has aggravated unemployment. From an initial position x_1 , U has increased to y_1 . Had the U function been a vertical line (*i.e.*, without expectation effect) unemployment would simply have moved leftward from x_1 , as price declined

⁹ It could, of course, be less than P_0 , since the U function has shifted leftwards. The implications of this possibility will become clear later.

and the vertical U function shifted leftwards. It should also be noticed that, at the new position y_1 , price is declining much faster than it would have declined at or near x_1 .

The next step is to trace out the subsequent courses of U, P, and P'. We shall assume that the price level effect is purely additive, *i.e.*, that the U function keeps its shape and moves leftward parallel to itself as price falls. And—solely to help keep track of our variables—we shall assume that equal successive percentage decreases in price cause equal absolute shifts to the left of the U function.¹⁰

We now introduce a clock and move the U function leftwards at a speed proportional to the value of P'. As the U function moves leftwards, P' decreases and the leftward speed of the function diminishes. We can keep a time series record of unemployment as we go.¹¹

When P has declined to P_3 , corresponding to the U function tangent to the P' function, the short-run equilibrium becomes unstable, and U moves *at its own adjustment speed* toward y_3 (which is itself receding as price continues to decline.) By "its own adjustment speed" we mean the rate at which U moves toward its own function value, the one which was relevant for movement from x_1 to y_1 .¹² From y_1 to y_2 , U moved at a speed geared to the rate of leftward shift (itself proportional to P') and the slopes of the two functions. (It might be that U's own adjustment speed were small relative to the rate of leftward shift; in that case U would always be limited by its own adjustment speed. We shall, in general, ignore this possibility.)

This movement from y_1 to y_3 is the conceptual reverse of the initial movement from x_1 to y_1 . What has happened is that price has already declined substantially, and it is the rate of price decline which is

¹⁰ That is, U is linear in the reciprocal of P.

¹¹ In this and the following paragraphs we make the very important assumption that the U *function* shifts slowly relatively to U's ability to adjust toward its function value, so that the intersection may be taken to denote the value of U. Strictly speaking, the value of U cannot be taken as lying quite on the function—else the value of U could not be changing. What we must envision is a rate of adjustment of U, toward its own function value, which varies with U's distance from its function value, rapid relative to the function's shift when U is any appreciable distance from its function value. And dU/dt may be taken, in short-run equilibrium, as given by $dU/dt = df/dt = f_P P' + f_{P'} P'' = f_P g(U) + f_{P'} g'(U) dU/dt$, or,

$$dU/dt = \frac{f_P g(U)}{1 - f_{P'} g'(U)}$$

where the numerator denotes the leftward shift of the U function, and the denominator allows for the slopes of the two intersecting curves. In the above notation we have written $g(U)$ for $P'(U)$ to avoid complication with primes; P' and P'' are time derivatives, $g'(U)$ is derivative of P' with respect to U.

¹² This speed is not taken to be constant (*cf.* n. 11) but rather as varying with the distance from the function value.

holding unemployment at a high level. As employment creeps up, the rate of price decline slows down sharply in the region where the P' function is steep, and a cumulative interaction sets in, a "multiplier effect" which finds U pushing its own function value ahead at a faster rate than U itself can adjust for some distance.

For a while, prior to tangency, there were three intersections, two stable equilibria with an unstable one between. At one of those price levels there were two possible equilibrium employment levels, each corresponding to a different rate of price change. Any autonomous jump of unemployment from one of these values to the other would have been a stable shift, *i.e.*, unemployment would have stayed fixed (in the short-run sense) at the new point.

According to the diagram, U then continues to move asymptotically toward zero, as P moves toward P_0 at a rate given by the P' function. Before comparing relative severities of unemployment, we may consider a few interesting points. One of them is the question: can unemployment, according to these hypotheses, oscillate? We had one reversal of direction at y_1 ; can there be another?

If the P' function has an ogive shape in each quadrant, *i.e.*, one inflection point in each quadrant, we have the result that U may reverse direction *but not more than twice*, aside from the original reversal at y_1 . If the U curve tangent to the P' curve cuts the horizontal axis to the left of the origin, the multiplier effect carries U over into the over-employment region, the south-west quadrant. This occurs because price has fallen below P_0 . In this case, U starts back along the P' curve in the south-west quadrant. (The intersection in that quadrant—if there is one—is necessarily stable.) The same thing can occur on the return trip, *i.e.*, a skip into the northeast quadrant. But, as the reader may test, it cannot then again skip back southwest so long as the P' function has the general shape imposed above. Whatever the shape of the P' function, so long as there are intersections in both quadrants, the number of oscillations is limited by the number of waves in the P' curve.¹³

It is also clear from the diagram that, if the system shows short-run stability, there is also long-run¹⁴ full employment stability. There is, however, the intermediate case, that for certain initial values there is short-run stability but after a finite time the process rolls off the track

¹³ Again our conclusion rests on the assumption that the U function slides slowly relatively to the speed at which U can adjust. Without this assumption perpetual oscillation may be obtained.

¹⁴ "Long run" as used here is the short run of usual analysis, *i.e.*, a period short enough that variations in the investment or consumption functions—other than those allowed for in the analysis—are susceptible of being ignored. Specifically, "long run" equilibrium refers to full employment and price P_0 .

and becomes unstable. This could occur if the tangent U function crossed the horizontal axis left of the origin and there were no intersection in the southwest quadrant. In that case initial unemployment would be aggravated by the "multiplier effect," check itself and start its orderly return along the P' function, and then "fly off on a tangent" into the overemployment side and keep forever going. This sort of thing could occur if the P' function failed to show symmetry about the

FIGURE 2

origin (which it need not), or could enter by the complication of the unemployment function's shape.¹⁵

Nothing will be argued here about the probable shapes of the functions. What has been demonstrated is that the expectation effect *need not* imply instability of full employment equilibrium, even though it does initially involve an increase in unemployment over what it would otherwise have been in the absence of anticipations. That is, whether

¹⁵ If we allow our behavior functions to apply even at zero employment on the one side, and some comparable physical limit on the other, then long run stability can be guaranteed so long as P' does not become infinite and we retain our assumption that U 's own adjustment is fast relative to the rate of shift of the U function.

the price-change effect leads to stability or instability has been shown to be an empirical question.

We shall now demonstrate the possibility that the expectation effect reduces the "severity" of unemployment. Of course, individual value judgments enter at this point if severity is a welfare problem. But probably all value judgments would allow that the magnitude of unemployment could be offset by its brevity, *i.e.*, that the height at its peak is not the sole measure of severity.

An attempt has been made on the second diagram to space the successive U functions proportionately to the height of the P' function, so that the various contour values of P denoted by the different U curves are equally spaced in time. (Here we make use of our simplifying assumption that U is linearly related to the reciprocal of P .) Similarly the cross ties on the horizontal axis, between the point x and the origin, are spaced horizontally in proportion to the values of P' corresponding to the values of U they denote. They represent successive unemployment figures, equally spaced in time, in the absence of the expectation effect, *i.e.*, if the U function is vertical. (The cross ties should be vertical U functions intersecting the P' curve; they are drawn as they are to keep the diagram clear.) We can compare now the two time series of unemployment under the two alternative assumptions of some, or no, expectation effect, by marking down the successive values of U corresponding to the successive intersections of the U and P' functions, going from right to left.

We have drawn a favorable case for our argument. If we introduce the expectation effect in the form of the curve labelled $U(P', P_1)$, we find that initial unemployment is about trebled. But we also find that it reduces, in two units of time plus some adjustment time (during the unstable phase from the point of tangency to z) to the amount of unemployment denoted by z . Without the expectation effect, P changes very slowly, and numerous units of time are apparently (the diagram is too coarse to permit counting) required for U to diminish to the amount z . Here we have procured, at the expense of severe unemployment for something over two units of time, a rapid fall in prices which brings us close to full employment, all through the agency of the "adverse" expectation effect.

A few other problems which share the form of that treated above may be suggested. If we suppose the rate of construction, X , related to the rent level, R , while the rent level itself is related to the stock of houses, S , and the national income, Y , we have: $X = X(R)$ and $R = R(S, Y)$. But the rate of construction is the time rate of change of the stock of houses, so we replace X by S' , obtaining $S' = S'(R)$, $R = R(S, Y)$. If next we suppose that a principal determinant of the

level of national income is the rate of construction itself, *i.e.*, $Y = Y(S')$, then we can rewrite our two relationships as: $S' = S'(R)$, $R = R(S, S')$, which is formally identical with the price flexibility formulation. If, as we probably intended, S' is positively related to R , while R is related negatively to S and positively to S' , the intersection of the two curves on our diagram will move toward a long-run equilibrium if dynamic stability is present—the only case in which the intersection is relevant.

Again, one might postulate (as we did above) that consumption is related to net assets as well as to the level of national income, and write $C = C(A, Y)$ to denote this. Letting Y , for simplicity, be the sum of consumption and investment, we then have $Y = C(A, Y) + A' = Y(A, A')$, for investment is simply the rate of change of assets (allowing for no price movements in the present case.) Then if we consider the level of income to be a principal determinant of the rate of investment, we have both $Y = Y(A, A')$ and $A' = A'(Y)$, which is formally similar to the price flexibility problem. In the present case we probably intend that Y is positively related to both A and A' , so the intersection on our diagram will move steadily outward, to no long run equilibrium, if dynamic stability is present. And again, if the curves so intersect that dynamic stability is absent, the two relationships will not be satisfied in the first place; the course of their moving intersection is consequently without significance.

This last example suggests a further extension of the technique. We may consider investment, as well as consumption, to be related to total assets and national income, so that $A' = A'(A, Y)$ and $Y = Y(A, A')$. In that case both our curves, that relating Y to A' for a fixed value of A and that relating A' to Y for a fixed value of A , would shift over time as A changed at the rate A' . If the curves are dynamically stable, then whether A , A' , and Y approach equilibrium depends on the relative shifts of the A' curve and the Y curve as A changes in value over time. (In this more complicated case, long-run equilibrium may be approached by some of the variables and not by others.)

WARBURTON VS. HANSEN AND KEYNES

By RENDIGS FELS*

In several recent papers, Clark Warburton has used statistical data on the velocity of money to defend traditional monetary theory and to dispute Keynesian theory.¹ His remarks raise five closely related problems, which will be discussed below: (1) the validity of the monetary theory of the cyclical downturn; (2) the validity of the theory that a shortage of investment opportunities causes the downturn; (3) the mutual consistency of the two preceding theories; (4) the validity of Keynes' theory of liquidity preference; and (5) the efficacy of monetary policy compared to fiscal policy.

1. Dr. Warburton has described the following sequence as causing the downturn; monetary deficiency leads to falling prices and *ipso facto* reduced profits and/or the expectation of losses; reduced profits cause the business downturn.² In other words, the peak in money supply relative to trend comes first, then the peak in prices, and lastly the peak of the business cycle. In the same article Dr. Warburton has provided statistical data on the quantity and circuit velocity of money with which the sequence can be verified for the period 1919-1945. The actual sequences are shown in Table I. In two cases (the downturns of 1929 and 1937), the sequence is borne out. In the other three cases, the peak in money relative to trend occurred virtually simultaneously with the cyclical peak, so that the sequence is not borne out. Neither is it satisfactorily disproved.

* The author is assistant professor of economics at Vanderbilt University.

¹ "Hansen and Fellner on Full Employment Policies," *Am. Econ. Rev.*, Vol. XXXVIII, No. 1 (March, 1948), pp. 128-34; "A Consideration of the Economic and Monetary Theories of J. M. Keynes: Discussion," *Am. Econ. Rev., Proceedings*, Vol. XXXVIII, No. 2 (May, 1948), pp. 293-95; "Quantity and Frequency of Use of Money in the United States, 1919-45," *Jour. Pol. Econ.*, Vol. LIV, No. 5 (Oct., 1946), pp. 436-50.

² *Journal Political Economy*, October, 1946, p. 443: "Monetary deficiency, either in the virulent form of contraction or in the milder form of absence of growth, is likely—in fact, almost certain—to produce a business depression. The reason for this is the well-known fact that wage rates and other business costs are largely fixed by contract or custom and that their downward revision is a slow and difficult process. A falling price-level therefore reduces business profits by narrowing the margin between the price of a product and its cost of production. The resulting absence of profit, or threatened loss, induces businessmen to reduce their output." In the March *American Economic Review*, Dr. Warburton holds that a rate of growth of the money supply slower than trend has the same effect.

Establishment of the expected statistical sequence is not sufficient to substantiate Dr. Warburton's theory. Even when the central bank has pursued a restrictive policy, as in 1937, it is possible that the slackening in the rate of increase in the money supply was caused by other factors, *e.g.*, the decline in net income-increasing expenditure by governmental units, which began in July, 1936,³ gives a plausible explanation both of the downturn of 1937 and the antecedent slackening in the rate of growth of the money supply.⁴

From a theoretical point of view, the milder position of Professor

TABLE I.—STATISTICAL TESTING OF DR. WARBURTON'S
MONETARY THEORY

Peak in Money Relative to Trend ^a	Peak in Wholesale Prices (BLS)	Peak in Business Cycle ^b
1Q 1920	May 1920	1Q 1920
2Q 1923	Mar. 1923	2Q 1923
2Q 1926 ^c	Nov. 1925	3Q 1926
2Q 1928	Sept. 1928	2Q 1929
4Q 1936	Apr. 1937	2Q 1937

^a Money held by business and individuals including time deposits, taken from Warburton, *Journal Political Economy*, October, 1946, pp. 438-41.

^b The dates of the cyclical peaks are taken, in accordance with Dr. Warburton's own preferences (*American Economic Review*, March, 1948, p. 130), from Arthur F. Burns and Wesley C. Mitchell, *Measuring Business Cycles* (New York, 1946), p. 78.

^c 3Q 1926 shows an increase which is less than trend by only a negligible amount. Total quantity of money, however, has a peak in 4Q 1925.

Haberler, who holds that inelasticity of the money supply makes the economy vulnerable to a downturn,⁵ seems sounder than the position of Dr. Warburton, who deems it a sufficient cause of the cyclical turning point. One must be very sympathetic indeed to the monetary approach to consider a rate of increase in the money supply of, say, 3 per cent (as compared to the trend rate of 4.5 per cent) a potent cause of depression.

2. In his comment on Professor Fellner's review of Professor Hansen's *Economic Policy and Full Employment*, Dr. Warburton has proposed an empirical test of the theory of shortage of investment opportunities *vs.* the monetary theory and has issued to Hansen, Fellner and any other interested economist three challenges:

a. To cite a single case [of a cyclical downturn], with supporting factual

³ Henry H. Villard, *Deficit Spending and the National Income* (New York, 1941), pp. 287 and 293.

⁴ Of course, the full story of 1937 is much more complicated.

⁵ Gottfried Haberler, *Prosperity and Depression*, 3rd. ed., (Lake Success, 1946), pp. 355-56.

data, which was not preceded by or simultaneous with monetary contraction relative to a reasonable rate of growth;

b. To cite a single case in which the monetary contraction associated with the down-swing was not itself sequential to (*i.e.*, preceded by) specific forces—such as central bank action, other government policies, or gold movements—which exercised a contractive influence on the effective quantity of bank reserves and the volume of bank credit outstanding or a direct contractive action on another important form of circulating medium;

c. To cite a single case, with supporting factual data, in which “idle money,” as indicated by a decline in circuit velocity relative to secular trend, preceded monetary contraction at the peak or in the early stage of the down-swing phase of the cycle.⁶

Contrary to Dr. Warburton's impression, failure to meet the three challenges does not damage the theory of inadequate investment opportunities as the origin of depression. With respect to the first and third, savers who are unable to find investment outlets might just as well be expected to repay bank debts (directly or indirectly) as to hold idle money.⁷ Moreover, inasmuch as Dr. Warburton has in mind primarily a decline in the money supply relative to a rising trend, it can be pointed out that gradual exhaustion of investment opportunities would be expected to slow down the rate of credit creation by the banks; for new investment both directly and indirectly stimulates the expansion of credit.

With respect to the second challenge, the presence or absence of specific forces having a contractive influence throws little light on the issue. Monetary deficiency in Dr. Warburton's sense could occur without such forces; on the other hand, where they do appear, they need not necessarily result in monetary deficiency.

Nevertheless, the data compiled by Dr. Warburton do provide evidence for one instance of idle money preceding both monetary deficiency and the downturn. In 1926, the peak in circuit velocity relative to trend preceded the peak in money supply relative to trend.⁸ The sequence depends on using, in accordance with Dr. Warburton's own preferences,⁹ the circuit velocity of the quantity of money held by business and individuals rather than the velocity of the total quantity of money. The total quantity of money gives no evidence of idleness prior to contraction.

⁶ *American Economic Review*, March, 1948, p. 131.

⁷ None of the references cited by Dr. Warburton contains any statement by Professor Hansen that idle money precedes either the downturn or monetary deficiency, nor do I know of any such statement by Professor Hansen.

⁸ *Journal Political Economy*, October, 1946, p. 439.

⁹ *Ibid.*, p. 447.

3. Dr. Warburton's presentation gives us a simple choice between two theories: the facts can support one or the other but not both. Actually, however, the facts can be (and usually are) consistent with both theories. It is this that makes it difficult in any given case to choose among alternative explanations for the downturn, and the statistical testing of business cycle theories is therefore apt to be unrewarding. Moreover, aside from the problem of interpreting events in any actual downturn, even in principle we may not be faced with a clearcut choice. We can, to be sure, say that the monetary explanation is correct if we know that a more elastic money supply would have indefinitely postponed the downturn whereas no increase in investment opportunities would have avoided it given the actual status of the money supply. Likewise, we can accept the exhaustion-of-investment-opportunities theory if we know that more investment opportunities would have avoided the downturn whereas no increase in the elasticity of the money supply would have done so. But it is possible that neither greater elasticity of the money supply alone nor more investment opportunities alone would have avoided the downturn. An eclectic can plausibly maintain, *e.g.*, that in 1929 (see below) the shortage of investment opportunities made a downturn inevitable but that an easier credit policy might have postponed it.

4. The preceding comments have concerned the cyclical downturn. Dr. Warburton's discussion of Keynes at the 1947 annual meeting of the American Economic Association by implication had to do with the expansion and contraction phases of the cycle. Dr. Warburton attempted to use the well-known fact that both the quantity of money and its velocity increase in the upswing and decrease in the downswing to disprove Keynes' theory that an increase in the money supply reduces velocity by bringing down the interest rate.¹⁰

In a similar vein, Dr. Warburton has criticized Professor Hansen

¹⁰ *American Economic Review*, May 1948, pp. 294-95: "In Keynesian theory, changes in circuit velocity of money are positively correlated with changes in the rate of interest, and changes in the rate of interest are negatively correlated with changes in the quantity of money. This means that changes in circuit velocity are negatively correlated with changes in the quantity of money, that is, V and M are compensatory, with additional supplies of money becoming 'idle' money. This contrasts directly with pre-Keynesian theory, according to which monetary expansion in excess of a normal rate of growth is accompanied, with some lag, by higher monetary velocity, and monetary contraction by hesitancy in the use of money; that is, changes in V were regarded by pre-Keynesian economists as a force accentuating rather than compensating the effects of changes in M .

"... Our study [at the Federal Deposit Insurance Corporation] has covered the period since 1918. The facts, we find, are in conformity with pre-Keynesian theory. The liquidity preference phase of Keynesian theory is not in accord with the facts, and appears to be irreconcilable with them."

Dr. Warburton does not give the statistics supporting his generalization.

for saying that there was a vast increase of money between 1934 and 1937 and that velocity was low.¹¹ According to Dr. Warburton, "From the low in 1933 to the high in 1937 the quantity of money increased relative to trend by less than 10 per cent, circuit velocity by more than 30 per cent. In terms of contribution to recovery—that is, to stimulation of sales at more than a normal rate of growth—the rising circuit velocity was more than three times as potent as the increase in the quantity of money."¹²

Dr. Warburton's position is open to criticism on two counts. First, on account of the usual *ceteris paribus* procedure in economic analysis, the liquidity preference doctrine cannot be discredited by a showing that historically increases in the quantity of money have been accompanied by increases in velocity. The essential question is, would not velocity have been higher in the period 1934-37, *e.g.*, other things being equal, had the money supply been smaller? No simple statistical analysis can answer the question. It may be that Dr. Warburton's investigations are more complicated than his comments at the annual meeting indicate, but it is doubtful if a complicated analysis would not be open to so much dispute that it could do little to settle the argument. Keynesians will remain convinced that federal deficits provided the driving force behind the expansion of 1934-37; that the increased velocity resulted from the rising levels of activity so generated; and that the chief effect of the increased money supply was to prevent velocity from increasing as much as it otherwise would.

Second, Dr. Warburton's statistical procedure is open to question. His figures indicate a relatively large increase in velocity and a small increase in money primarily because he removes trend. His trends, which are straight lines, apparently are based on the period 1919-29 and are projected into the period 1930-45.¹³ It is true that the trend for velocity gives a good fit to the actual data for the later period, but Dr. Warburton's assumption that the same forces which produced a straight-line downward trend in the 'twenties continued to operate at the same rate in the 'thirties is dubious. It can equally well be assumed that the principal force making for a downward trend in velocity in the period 1919-29 was a rise in per capita real income;¹⁴ as real

¹¹ Alvin H. Hansen, *Economic Policy and Full Employment* (New York, 1947), pp. 224-25.

¹² *American Economic Review*, March, 1948, p. 133. Dr. Warburton's statistics, which compare the low of 1933 with the high of 1937, are a bit unfair to Professor Hansen, whose statement referred only to the period 1934-37. Thus Dr. Warburton introduces into his figures the sharp rise in velocity between the 1st and 2nd quarters of 1933.

¹³ *Journal Political Economy*, October, 1946, p. 447.

¹⁴ This is, in fact, Dr. Warburton's own opinion (*ibid.*, p. 443).

income per capita even in 1937 did not regain the 1929 level, it would be expected that the downward trend would be mitigated; and therefore the velocity in the period 1934-37 was low.

The trend for quantity of money, when projected into the 'thirties, does not give a good fit at all. Even if it did, one could still maintain that the forces producing the upward trend in the 'twenties—population growth, increased productivity per capita, and the forces increasing the ratio of cash holdings to expenditures¹⁵—were not operating nearly as strongly in the 'thirties. Therefore, the fact that there was more money and less money-income in 1937 than in 1929 indicates a large growth in the money supply.

Moreover, it seems to me (though Dr. Warburton will doubtless disagree) that the true state of the money supply in those years cannot be measured by the quantity of money alone. The large growth of member bank excess reserves and the low rates of interest show that the quantity of money could have been much larger. Hence, for purposes of the present problem, Dr. Warburton's statistics understate the money supply and overstate its velocity. Some fraction (or multiple) of the excess reserves could be regarded as idle money.

5. Concerning policy, Dr. Warburton says, "A compensatory fiscal policy, carried out in a manner producing appropriate effects on the quantity of money, may be an antidote to a dose of improper monetary policy; but with proper monetary policy exercised through ordinary central bank operations, an antidote will not be required."¹⁶

As the arguments for and against the effectiveness of monetary policy have occupied a large part of the literature of the last twenty years, it would not be profitable to review them here, but two observations may be made. First, most economists would blame the downturns of 1920 and 1937 more on fiscal policy than on monetary policy. In both cases the balancing or overbalancing of the federal budget was a major factor. Second, the extreme form in which Dr. Warburton has stated his position appears to be untenable. He gives the appearance of believing that cyclical downturns can be avoided simply by pursuing an easy money policy. If this be a misinterpretation, it is one to which his remarks are open and should be corrected.

The experience of 1920 and 1929 shows that continuance of easy money would probably have been just as disastrous, if not more so, than the restrictive policies actually adopted. Easy credit might have permitted the inventory boom of 1919-20 to continue a while longer, but it is not likely that a smooth transition to a slow rate of inventory

¹⁵ *Ibid.*, p. 444.

¹⁶ *American Economic Review*, March, 1948, p. 134.

accumulation could have been effected, especially in the face of the decline in export markets. The first evidence of coming deterioration of the price level would (and did) end new investment in inventories and initiate cyclical contraction. In 1929, credit expansion could have helped business only at the cost of furthering the stock market boom and making the crash so much the worse. Conversion of paper profits into realized losses as brokers demanded more margin was bound to have serious effects on both consumption and investment. In boom times monetary policy is up against the familiar dilemma that action to curb excesses containing the seeds of depression may fatally injure legitimate business. In such cases, "ordinary central bank operations"—to use Dr. Warburton's phrase—are insufficient.

THE LEARNED HANDMAIDENS OF AMERICAN CAPITAL.

A Survey of Literature*

By A. AYZENSHTADT

Translator's Preface

The United States and its economists have become quite a popular subject in the Soviet economic literature since the end of the war. A number of books have been published (particularly by the former Institute of World Economy and World Politics), and hardly a journal issue comes out without at least one article devoted to economic conditions and economic thinking in the United States. A study of these writings offers the American economist the unique pleasure of seeing himself and his environment in a peculiar mirror, though the images, to put it mildly, may often cause surprise; it also gives him valuable information both for the understanding of the Soviet Union and for the understanding of himself.

The article translated here appeared in the July-August (No. 4) 1947 issue of the Soviet journal *Planned Economy* (*Planovoye Khozyaystvo*), which is published bi-monthly by the State Planning Commission (Gosplan). It was selected for translation because of its interest: in a rather short space, the author covers some of the most important ideas discussed in Western economic literature in the works of Schumpeter, Hansen, Keynes, Ezekiel and others. The interpretation of these ideas by a Soviet economist is most instructive. But I hope the reader will avoid the error so often made by Soviet economists in regard to our own literature, that is, of treating this article as *the* official pronouncement on the subjects covered. Though the range of economic opinion in the Soviet Union is much more narrow than in the United States, differences as witnessed by sharp debates (such as the Varga discussion) do exist. Mr. Ayzenshtadt's essay is not unrepresentative, though possibly it is more imaginative than the average. Yet I earnestly hope that the reader will abstain from generalizing too readily about Soviet economic literature on the basis of this *one* paper. Translations of Soviet economic works are beginning to appear; perhaps this article will be followed by others. There will be plenty of time for generalizations.

A few remarks about Soviet economic periodicals may help to set this paper in its proper perspective. The so-called professional journals in this country are essentially written by economists for economists. The Soviet economic periodicals, on the other hand, concentrate not so much on the development of economic science as such, but rather on the interpretation, with a definite political objective, of economic and statistical information for a more general audience. In his interpretation of economic facts and ideas, the Soviet economist is not supposed to treat his material with impartiality and objectivity; the latter word has acquired an invective meaning in the Soviet Union. His rôle is that of an intellectual crusader, actively engaged in the building of socialism at home and in combating its opponents ("unveiling" is the favorite term) abroad. Yet an economist cannot help being a scientist,

*Translated by Evsey D. Domar, associate professor of economics, The Johns Hopkins University.

at least to some extent, and the conflict between the two rôles—crusader and scientist—has been sharp. The recent denunciations of so many books on economics and statistics (also on philosophy, history, and biology) published in the Soviet Union since the war, show that the conflict is far from being resolved. The present paper, however, does not appear to bear any marks of this conflict.

Since the subject matter of Mr. Ayzenshtadt's paper is rather controversial, I endeavored to steer as close to the original as I could. To replace the author's translations of English passages, I tried to use the originals, rather than to re-translate them into English whenever his translations were reasonably close to the originals and a proper reference was given or could be easily found. In other cases the techniques used were stated in the footnotes.

When a translator, who happens to be an economist himself, works on a paper like the present one, there is an urge (for reasons which will presently become obvious) to start an argument with the author. I felt, however, that such an attempt on my part would destroy the unity of the article and spoil the fun for the reader, who might like to do it on his own. Therefore my notes were limited to a few easily ascertainable and trivial points. For the rest, let the article speak for itself.

E.D.D.

The present state of thought among bourgeois economists is a reflection of the conditions in which the bourgeoisie finds itself in the era of the general crisis of capitalism, when due to the Second World War, capitalist contradictions have become particularly acute. More and more frequently, "investigations" of bourgeois economists are aimed at finding ways of overcoming these contradictions and of averting crises, in order to save capitalism from its imminent destruction. All these investigations exhibit the complete bankruptcy of the bourgeois economic "science," its inability to understand the real contradictions of the capitalist society, and the hopelessness of the bourgeois economic prescriptions for rescuing capitalism. The vulgar, apologetic meaning of all these theoretical constructions acquires an ever stronger reactionary character;¹ it demonstrates the irrefutable fact that the contemporary bourgeois political economist is merely the learned handmaiden of monopolistic capital who is assigned the task of constructing "scientific" foundations for the capitalist reactionary policies against the working class, and for the capitalist-imperialist expansionist aspirations.

And if some contemporary bourgeois economists speak about the contradictions and instability of the capitalist economic system, they do so only because these contradictions are already so obvious that they can no longer be concealed. Their admissions are significant only to the extent that they bear witness to the bankruptcy of the bourgeois political economy which can deny no longer the crying contradictions of capitalism, the harmony of which it had extolled over many decades. But these same economists firmly cling to their reactionary positions and insist on the retention of capitalism as such, and of the system of enslavement and oppression of the toiling masses based on it. Those who dare to mention the question of capitalist contradictions

¹Translator's note: The word "vulgar" is evidently used here as it was used by Marx, in the sense of popular, superficial, shallow.

make every effort to minimize them; and in particular they avoid using the word "crisis."

One of these authors is an American professor, Benjamin Higgins. Here is what he says:

Our economy at war's end may be likened to an acrobat performing on a very thin wire called "economic stability." On one side yawns the Abyss of Depression, on the other roars the Volcano of Inflation. The performer is blindfolded, his faltering footsteps guided by shouts from a crowd of professional economists, legislators, and voters who together formulate economic policy. The acrobat is hampered in his movements by the long pole in his hands, weighted at one end with "excess purchasing power" and at the other with "excess saving," which he raises and lowers in response to the cries that are loudest. After the last war, our acrobat seemed in danger of falling into the Abyss, gave more weight to "purchasing power" and fell into the inflationary volcano instead; subsequently plunged into the Abyss in an attempt to compensate, rebounded, maintained his equilibrium for a few years, but, his strength meanwhile giving out, he collapsed into the Abyss in 1929 and only a *strong draft of "major war" revived him.*²

Higgins does his best to avoid using the term "crisis," replacing it by the concept of a "depression." This is a favorite method of bourgeois economists, in their attempt to eliminate crises from the analysis of the capitalist cycle. At the same time, Higgins finds the causes of this "depression" in a superficial relation between "excess purchasing power" and "excessive savings," thus completely avoiding the question of class contradictions in the bourgeois society.

Other bourgeois economists echo Higgins. Thus Leon Henderson writes in his report on "Enterprise in Postwar America":

There are several targets that are set. There is one target which ought to be in front of us all the time, and that is the target of the disaster of the thirties; the stagnation and our failure to find a way out of our difficulties. No matter what our status is, no matter what we are in the way of policy maker or policy receiver, we should be constantly thinking of how ashamed we should be that it took a war and seven and a half billion dollars per month of spending before we could have full employment. That is a target anybody can shoot at.³

Thus these "strong words," like "shame," "targets," etc., are used only to emphasize the author's desire to defend from fire the unmasked "target" of capitalism.

³ Leon Henderson, "Enterprise in Postwar America," *Postwar Goals and Economic Reconstruction* (New York University, 1944), pp. 16-17.

Translator's note: Mr. Ayzenshtadt's translation of this passage was rather free and made it considerably stronger than the original.

Notwithstanding the fact that some bourgeois economists describe capitalist contradictions more or less frankly, they still hold on to their capitalist positions and make every effort to solve the insoluble problem: how to overcome these contradictions within the framework of the capitalist system. Moving in this magic circle, many of them invariably arrive at reactionary conclusions in which the apologetic character of the bourgeois economic thought clearly manifests itself.

Particular attention is devoted by bourgeois economists to find ways of "curing" capitalism of its crises. The *Readings in Business Cycle Theory*, published by the American Economic Association in 1946, is very significant in this respect.⁴ The problems of employment and of crises occupy the center of the stage. The authors are American followers of Keynes.⁵ Their aim, to use their own expression, is to "iron out" the industrial cycles, or at least to mitigate them.

"The business cycle was *par excellence* the problem of the nineteenth century," says A. Hansen. "But the main problem of our times, and particularly in the United States, is the problem of full employment" (p. 370). The two problems are indissolubly connected. If industrial development took the form of a continuous stream, says Hansen, the problem of "full employment," would be settled once and for all. The sizeable volume of 494 pages, composed by Hansen and his associates, is devoted to an effort, which—as one should have expected—proves to be completely fruitless.

The essays composing the volume were written during the period 1923 to 1941, and thus cover three cyclical crises: 1921, 1929 and 1937. (The book itself came out in August, 1946.)

Of the twenty-one essays, only three are directly concerned with the theory of crises. The others analyse Keynes' theory about a "planned" state capitalism and full employment as "universal measures" against crises.⁶

The first three essays are reprints of older articles. They try to propagandize the bourgeois apologetic theory of "long cycles," a theory discredited in the USSR a long time ago.

The reader is aware that this notorious theory of "long cycles" represents an attempt on the part of the outrageous defenders of capitalism to "refute" the irrefutable fact that capitalism develops through periodic crises of over-production which repeat themselves every seven to ten years.⁷

It is for the specific purpose of describing capitalist development as a process deprived of the inevitable capitalist crises, that American economists

⁴ Translator's note: The volume was published in 1944. The author evidently had a copy printed in August 1946.

⁵ Translator's note: Some of the authors, such as Schumpeter, Kondratieff, or Haberler might decline this honor. Of the twenty authors, at least six could not be possibly classified as American. Of the remaining fourteen, as far as I know, only seven are *not* of foreign background.

⁶ Translator's note: Eight essays are not concerned with Keynes, seven of them having been published before 1936.

⁷ Translator's note: The theory in question belongs to Nikolai D. Kondratieff, a Russian economist whose name should undoubtedly be familiar to Mr. Ayzenshtadt.

have found it necessary to rescue from oblivion the "long cycles," in which the true cyclical character of capitalist development is "straightened out" and dissolved.

It is quite significant that we find the German economist Joseph Schumpeter, who is now doing such great things at Harvard University, in the role of the newly ordained preacher of this apologetic theory of "long cycles." Not satisfied with the "scheme of three cycles" (long, medium and short), Schumpeter, in his paper "The Analysis of Economic Change," invents still another one—the "theory" of "secondary cycles." The real purpose for which these "secondary cycles" are invented is the same as for the "long" ones: to conceal the true cycles which are connected with the crises. Economic life is thus transformed into an uninterrupted flow of small oscillations, a continuous vibrating movement without such shocks as crises. Schumpeter considers it possible, with foreign markets and Free Trade, to "iron out" the crises in the United States, which, according to his own admission, take a much more violent form than those in England.

Another author, Hans Neisser, who found refuge at the University of Pennsylvania, revives Say's Law regarding the impossibility of general overproduction. ". . . Say's contention of the impossibility of general overproduction," says Neisser. "seemed contradicted by the recurring experiences of severe crises" (p. 385).

Neisser, however, easily removes this contradiction by postulating the possibility of partial overproduction in both the spheres—of the production of consumer goods and of the production of means of production. He finds the remedy to this situation in foreign markets. In terms of concrete policy, this means that American imperialism can escape crises by conquering an ever larger number of foreign markets.

* * *

The central figure of the volume is Keynes. Eighteen papers are devoted to the analysis of his theory. The whole discussion is concentrated around his name.

What is the explanation of the influence that he exerted on world bourgeois economic thought, and particularly on American economists and American economic policy during the war? The explanation lies in the fact that Keynes' vulgar theory of the stimulating effects of investment leads to the conclusion that the cost of the increased investment should be borne by the working class. Keynes transformed economic theory into a powerful weapon of economic policy to be used by the bourgeois state against the toiling masses.

His point of departure is the presence of large unemployment, which is characteristic of the period of the general crisis of capitalism. His central idea is that the level of employment depends not on the conditions of capitalist production, but on the accumulation of money capital and on the magnitude of investment. All of Keynes' flimsy arguments ignore the process of capitalist production as such; attention is concentrated on the process of circulation only. This is the reason why Keynes' whole analysis has such a superficial, vulgar character.

Marx had foreseen the possibility that superficial bourgeois economic thought would suffer from such an optical illusion. Analysing the process of reproduction and circulation of total social capital Marx wrote that money capital "is the form in which every individual capital appears upon the scene and opens its process as capital. It therefore appears as the prime promoter, giving the first impetus to the entire process."⁸

Still more strongly does Marx reprove this sort of nearsightedness on the part of bourgeois political economy in his chapter on "The General Law of Capitalist Accumulation": "The superficiality of Political Economy shows itself in the fact that it looks upon the expansion and contraction of credit, which is a mere symptom of the periodic changes of the industrial cycle, as their cause."⁹

Even the greatest admirers of Keynes and of his theory that loan capital is the main propeller of the industrial cycle, do not see anything new in it. "As most theories of business fluctuations, in their explanation of changes in employment, concentrate attention on changes in the volume of investment, Keynes' emphasis on this latter point is not new."¹⁰

Keynes himself thinks that the "novelty" of his system lies in the equilibrium formula of the economic process, in which the independent and dependent variables are arranged as follows:

Independent variables

1. Propensity to consume
2. Marginal efficiency (profitably) of capital
3. Rate of interest
4. Liquidity preference

Dependent variables

1. Saving
2. Investment
3. Level of employment

When the marginal efficiency of capital is low, the capitalist prefers to hold his wealth in liquid form rather than to invest it. Enter the worker, who tightens his belt, abstains from his propensity to consume, and accumulates his savings. As a result, money, and hence loan, capital increase, the interest rate falls, the cost of credit slides down almost to zero; now investment goes up and so does employment. Thus the worker himself has provided the funds for his own exploitation. Having rendered the surplus value to the capitalist once before, he now takes off an additional portion of his wages to invest it in production.

Thus the "curbing of the propensity to consume" applies not to all social

⁹ K. Marx, *Capital*, Vol. I (1936 ed.), Chap. XXIII, p. 540. Translator's note: In the Kerr edition, this quotation appears in Chapter XXV, p. 695.

¹⁰ Bertil Ohlin, "Some Notes on the Stockholm Theory of Savings and Investments," *Readings in Business Cycle Theory* (Philadelphia, 1946), p. 125.

classes, but to workers only. The formula for the increment of income is constructed by Keynes in the following manner: increment of income = increment of consumption + increment of investment.

Income, consumption and investment are expressed by Keynes in wage units. A wage unit is the payment for a unit of labor, for an hour of common (unskilled) labor. The payment for an hour of this labor is the wage unit used by Keynes as a common denominator. Keynes expresses not only the income of workers, but that of capitalists as well in terms of this unit; thus he is able to misrepresent the real essence of class relations in a capitalist society.

The increment of saving is also expressed in terms of this "wage unit." In general, Keynes defines saving as the difference between income earned during a certain period and consumption of the same period.

The main purpose of all this theorizing is to find a method for curbing the "propensity to consume" of the working class. With this aim in mind, Keynes introduces a new concept—the "investment multiplier" showing that as saving and investment increase, income rises at a faster rate than investment.

It is this situation that is supposed to induce the worker to part with his savings.

Keynes' theory is constructed as a special equilibrium system which does not allow for sudden explosive crises. Keynes asserts its universality and its continuous effectiveness throughout the whole period of the existence of capitalism.

The system is peculiar in the sense that its equilibrium depends on factors which are very unstable by themselves. Besides the objective factors—the rate of interest and the marginal efficiency of capital (*i.e.*, that profit level below which the bourgeois does not wish to descend)—two subjective or psychological factors are operating as well: the liquidity preference and the propensity to consume. The former means that the capitalist prefers to hold on to his money, because he fears risking it in investment; the latter, that the worker must combat his propensity to consume in order to throw his money into production. Both are factors not easily determined and regulated.

Keynes, though regarding himself a "great revolutionary," admits with perfect frankness that his theory aims at preservation of capitalism. ". . . The foregoing theory is moderately conservative in its implications. For whilst it indicates the vital importance of establishing certain central controls in matters which are now left in the main to individual initiative, there are wide fields of activity which are unaffected," says Keynes in the chapter on the social philosophy to which his "General Theory" might lead.¹¹

According to Keynes, the regulatory activity of the bourgeois state should first of all extend control over saving, and secondly, it should "socialize investment."

¹¹ J. M. Keynes, *The General Theory of Employment, Interest and Money* (New York, 1936), Chap. 29, "Social Philosophy towards which the General Theory might lead," p. 377.

But the phrase "socialize investment" is just empty chatter, since Keynes defends the inviolability of private ownership in the means of production.

. . . It is not the ownership of the instruments of production which it is important for the State to assume. If the State is able to determine the aggregate amount of resources devoted to augmenting the instruments and the basic rate of reward to those who own them, it will have accomplished all that is necessary (p. 374).¹²

That the state should be used as the weapon for forcing a reduction in the consumption of the toiling masses, and for guarding capitalists' profits is the real meaning of all of Keynes' "social philosophy" and all his so-called "socialization of investment."

During the war, Keynes came into the open. In his pamphlet *How to Pay for the War* he directly and frankly posed the question not as "how" to pay, but as "who" shall pay. He further stated that the rich could not pay. It is clear then that the working class must pay. A whole chapter was devoted by Keynes to this question.

His plan contains the famous theory of compulsory saving, which was carried into effect not only in England, but also in Canada and in the United States. A direct quotation will show how Keynes justifies the necessity of financing the war at the expense of the workers:

. . . It is not sane to suppose that the war can be financed without putting some burden on the increased war incomes of the class with £5 a week or less. . . . The incomes of this group will have increased on the average by some 15 per cent as a result of the war. Is it seriously expected that those with less than £5 a week will be allowed to increase their average consumption by 15 per cent, while those with more than £5 (for example with £1 million—A.A.) a week will be left on the average with only a quarter of their incomes to consume?¹³

Keynes' plan is an offensive against the standard of living of the working class. It is a bourgeois program which strives to burden the working class with the whole weight of the costs and losses of the war and of the crises.

* * *

The leader of American Keynesians is Alvin Hansen. We should note, however, this difference: for Keynes, the movements of saving and investment are secondary factors, the primary ones being the "propensity to consume," and the "liquidity preference"—both purely psychological. For Hansen, on the other hand, it is the periodic accumulation and exhaustion of loan capital that is the cause of the fluctuations of the industrial cycle.

Hansen's main proposition is that full employment and the maximum level of income that can be achieved in a contemporary private enterprise economy, are impossible without a sufficient volume of investment—sufficient, that is,

¹² Translator's note: I found this passage on p. 378.

¹³ J. M. Keynes, *How to Pay for the War, A Radical Plan for the Chancellor of the Exchequer* (London, 1940), Chap. IV, "Can the Rich Pay for the War?", pp. 25-26.

to fill the gap between consumer expenditures and that level of income which a full utilization of all factors of production can produce.¹⁴

To raise the effective demand (purchasing power) through increased investment and thus to achieve full employment—this is Hansen's program, echoing Keynes word for word.

Compensatory action against cyclical fluctuations should be undertaken by the state budget in the form of "deficit financing." This paradoxical and absurd conception of the sources of funds has earned a prominent position in American economic literature. Hansen has developed his theory of deficit financing, *i.e.*, of an enormous growth of the public debt, at considerable length in a number of pamphlets published while he was a member of the National Resources Planning Board.

In a pamphlet entitled "After the Defense—What?", Hansen develops the idea that a continuously growing public debt allegedly creates full employment and prosperity.¹⁵ Financial costs can be disregarded, because, if maximum production and full employment can actually be achieved, the rise in production will pay for the needed expenditures: "doing the job pays the bill." In other words, it is not a question of money, but of manpower, material resources and organization. Hansen is confident that a full realization of the productive potential in a capitalist society is possible; therefore the government should engage in ever larger expenditures to stimulate production. He is also confident that "every cent expended, public or private, becomes income for the members of our society. This conception apparently explains," says Hansen's critic Moulton, "the statement of the National Resources Planning Board that costs are of no significance, that 'doing the job pays the bill.' Since the receipts are necessarily identical with the disbursements everything is satisfactory: cost equals income; and income equals cost."¹⁶

Here Hansen revives the erroneous notion of Adam Smith identifying total social product with national income, a notion long since discredited. Identifying production with income, Hansen seeks to solve the problem of crises by public investment and an unlimited growth of the public debt. To replace the expression "treasury deficit covered by borrowing," which would reveal the essence of his budgetary policy, Hansen has coined a vague but well-sounding term "net income-creating expenditures."

The "novelty" of Hansen's theory simply is that debts need not be paid. In other words, this is a "theory" of state bankruptcy raised to the level of a system. In an article published in *Fortune* in November 1942, Hansen tries to show that the public debt is not really a debt.

¹⁴ Alvin H. Hansen, "Economic Progress and Declining Population Growth," *Readings in Business Cycle Theory* (Philadelphia, 1946).

¹⁵ Translator's note: This pamphlet was published by the National Resources Planning Board in 1941. It does not bear Hansen's name and I understand from him that he did not write it. Perhaps the author referred to another pamphlet—*After the War—Full Employment*, which was published under Hansen's name in 1942.

¹⁶ Harold G. Moulton, *The New Philosophy of Public Debt* (The Brookings Institution, 1943), p. 60.

This means that mutual credits of capitalists must be honored, but the state need not repay its debts to the people. Thus the public debt becomes simply an instrument of the bourgeois state for robbing the toiling masses. This is the class essence of this new-fangled "theory" of the unreality of the public debt.

Naturally, this "theory" of the public debt has found followers who have carried it to absurdity. Thus, Professor Seymour Harris writes:

. . . A public debt of \$4,000 billion was compatible with the maintenance of the capitalist system. . . . It is conceivable that a debt of these proportions could be accumulated over a period of 50 to 60 years, without the emergence of a serious inflation. . . . The major part of the debt would be financed out of savings, not out of the creation of further new debt.¹⁷

The achievement of the astronomical figure of 4,000 billion dollars (the war debt did not exceed 258 billions) appears to Harris to be possible within the capitalist system, since a method has now been found for "overcoming" the crises in the growth of the public debt itself.

This approach is not at all new. It had been tried before. Let us recollect what Marx had to say about Pitt's financial policy:

The idea of capital as a self-reproducing and thereby self-expanding value, lasting and growing eternally by virtue of its inherent power . . . has led to the fabulous fancies of Dr. Price, which far outdo the fantasies of the alchemists; fancies, in which Pitt seriously believed and which he used as pillars of his financial administration in his laws concerning the sinking fund.¹⁸

Under the pressure of military necessity, the American government had to find salvation in an ever-growing public debt, just as Pitt did in his time. It is impossible, however, not to be amused at the philosophising of Hansen and Harris which exactly repeats, after 150 years, the fantastic fabrications of Dr. Price.

It is true, nevertheless, that Hansen realizes all the inconvenience of debt repudiation, particularly for a country as wealthy as the United States. He has therefore come up with a new variety of compensatory policy, this time not based on borrowing.

This policy seeks to solve the crisis problem by adjusting the government budget to business fluctuations. During prosperity, the government should accumulate a surplus, and then spend it when depression comes. The application of this policy Hansen prudently restricts to state and local governments; they are the ones to set up reserves in anticipation of a crisis.

This theory has had considerably less success than the "new philosophy

¹⁷ Seymour E. Harris, *The Economics of America at War* (Harvard University, 1943), pp. 383-84.

Translator's note: The last sentence was translated by Mr. Ayzenshtadt as follows: "The major part of this debt can be covered by savings without a repayment of previous debts at the expense of new ones." The book was published by W. W. Norton & Co., Inc.

¹⁸ K. Marx, *Capital*, Vol. III, Part I (1932 ed.), p. 279. Translator's note: In the Kerr edition, this quotation appears in Vol. III, Part V, pp. 463-64.

of the public debt" for two reasons: (1) state governments have deficits anyhow, and local governments have to borrow frequently; (2) attempts to induce workers to set up surpluses in the budgets of their local governments, over and above compulsory savings, cannot be successful; as for the propertied classes, they have protected themselves with the "liquidity preference."

Professor Benjamin Higgins, quoted above, writes that 38 states have created "planning boards for post-war public works." But not a single state set up the needed reserves. Projects worth 18 billion dollars have been submitted to the Federal Works Agency, which in turn distributed them among its regional offices. "They are reposing there gathering dust."

This is just one of the numerous manifestations of the helplessness of the bourgeois economic science, and of the inability of capitalism to engage in economic planning.

* + *

The volume *Readings in Business Cycle Theory* ends with Ezekiel's paper under the significant title of "The Cobweb Theorem."

In essence, this is a discussion of the chronic world agricultural crisis which accompanies the general crisis of capitalism. Ezekiel, however, bypasses this problem. He narrows down his topic to a study of "laws of commodity price movements which are subject to their own fluctuations, independent of the general industrial cycle. Such are prices of agricultural products."¹⁹

These prices, following laws of their own, are established, according to Ezekiel, at the exact point of intersection of demand and supply. Numerous diagrams illustrate the formation of prices of bacon, corn, but particularly of hogs; the last case is furnished with a lengthy bibliographical list of the works of German economists who preceded Ezekiel. The theory of price determination as a result of interaction between supply and demand belongs to Marshall, whose student Ezekiel is.

Ezekiel calls his diagram the "Cobweb Theorem," because the intersecting curves of supply and demand create a pattern similar to a cobweb.²⁰ Establishing his "hog prices prognosis" in this manner, Ezekiel adds, to all preceding psychological and mathematical theories, one more fantastic explanation of reality, this time in the garb of a cobweb.

We may say that this "Cobweb Theorem" is, in a sense, a symbol uniting all theoretical models of the *Readings in Business Cycle Theory*. This theorem beautifully characterizes the complete theoretical helplessness of the bourgeois economics, its complete inability and unwillingness to find a scientific explanation of those basic contradictions in which capitalism is enmeshed.

All these constructions are cobwebs which fly to bits as soon as they are touched by scientific critique. And yet, the cobweb is being continuously

¹⁹ Translator's note: I re-translated this quotation into English. No page was given, and I could not find the corresponding passage in Ezekiel's paper.

²⁰ M. Ezekiel, "The Cobweb Theorem," *Readings in Business Cycle Theory* (Philadelphia-Toronto, 1946), p. 422.

re-created, because inside of it there is a live beast—the spider—monopolistic capital.

The tragedy of the situation is realized by the author of the "Cobweb Theorem" himself. He concludes his essay with these words:

The cobweb cycles (not to any lesser degree than other fluctuations analyzed by Keynes) prevent the system from reaching its most effective utilization of resources.

The contemporary system is not an automatic self-regulating mechanism, which can provide full utilization of resources. Unemployment, excess capacity and wasteful use of resources—these are its constant companions.²¹

Thus does the bourgeois economic thought, attempting to solve the "full employment" problem, confess to the hopelessness of its theoretical constructions. And yet, over one-sixth of the globe, the problem of full employment, which the bourgeois economists are hopelessly tackling, has long since stopped worrying man's mind. Here the solution is re-enforced in the words carved in granite of the 118th section of the Stalin Constitution: "The right to work is guaranteed by the socialist organization of the people's economy, by the inevitable growth of the productive forces of the Soviet Society, by the elimination of economic crises and by the liquidation of unemployment."

* * *

In their quest for ways of preventing crises, contemporary bourgeois economists do not stop at internal measures only. Exceptionally high hopes are reposed in the imperialistic expansion of monopolistic capital. The intensification of the expansionist policy of American imperialism after the second World War and its drive for world domination are reflected not only in the notorious "Truman Doctrine" and "Marshall Plan," but in the theoretical constructions of American economists as well.

Two books, published simultaneously under nearly identical titles are significant in this respect. The first—*American's Place in the World Economy*—belongs to the New York University Institute on Post-war Reconstruction; the second—*America's Role in the World Economy*—was written by Alvin Hansen, with whom we are already familiar. Hansen's book is mostly concerned with the accumulation of money capital in the United States, and with the possibility of transforming it into real capital by means of capital exports. The New York University volume is mainly devoted to the second part of the problem—capital exports and their prospects.

Clarence Senior (the expert on "Pan-American" economics) states the problem very categorically:

We are doubly armed for the penetration of other countries. First of all our role as suppliers of machinery and technique is facilitated by the fact

²¹ Translator's note: Ezekiel does not conclude his essay in this manner. Several sentences can be found on his last page (p. 442) which, when put together, approximately yield this quotation. The last five words are an exception. As far as I can tell, their authorship belongs solely to Mr. Ayzenshtadt. It seems to me that this conglomeration of sentences with a new ending has produced a stronger and different effect than the one intended by Ezekiel.

that after the war we will have about half of the productive capacity of the world, plus outstanding institutions for technological training. Secondly, we are equipped to play our role as investor by the possession of more than half (more correctly $3/5$, i.e., 21 billions out of a total of 35) of the world supply of gold; plus a tremendous capacity for capital formation. In the early postwar years, most of Latin America will not need government loans; but long-range development projects are needed and are being planned in all of the countries to the South.²²

A wide field for the utilization of American capital and for the strengthening of American claims to world domination is found by Morgan Lewis in his proposed construction of a transcontinental railroad, crossing the whole American continent and connecting United States with Central and South America. This transcontinental railroad, nine thousand miles long, is aimed at the "acquisition of natural resources of the wealthiest countries of South America. It will be inconvenient, of course, to finance this line by United States government appropriations; it should be therefore financed by private investments"—and thus create ample scope of action for United States monopolies.²³

The scope of Lewis' imperialistic ambitions is very broad indeed. To recover the cost of the construction of this railroad, he suggests the following operation: Large, uninhabited areas in South America, which according to his estimates, stretch for hundreds of square miles, will be purchased and then re-sold at a profit (their prices having been sharply raised by the railroad). This operation, undertaken by United States capital, should cover all the costs of this great expansionary plan in South America, and leave a handsome profit besides.²⁴

Hansen approaches the problem somewhat differently. First of all he establishes the fact that the 21 billion dollars worth of gold "sterilized" and buried in the basements of Fort Knox²⁵ is unprofitable by itself, while its

Translator's note: I re-translated the quotation trying to use as many of Mr. Senior's original sentences as I could find. The statement as a whole does not appear on p. 244. There are scattered sentences on pp. 243-44 conveying approximately the same idea.

²³ Morgan J. Lewis, *Key to a New America* (American Progress Association, Philadelphia, 1941), p. 11. Translator's note: See Note 24.

²⁴ Translator's note: Page 11 of Lewis' book does not contain the quotation referred to in note 23. The railroad uniting the Americas is discussed in Chapter XIV, pp. 89-99. The nearest quotations I could find on the two questions touched upon by Mr. Ayzenshtadt are as follows:

"There probably are some inter-governmental reasons why the United States government could not build this super railroad to the southern countries, but there is no reason why a private corporation, financed with American money and some money from the citizens of the countries it would run through, could not finance it" (p. 91).

"There are some uninhabited sections in South America one hundred miles square that could be purchased from the governments now owning them. The natural resources from these regions could be sold at a profit which would more than pay for the 9000 miles of a Super International Railroad" (p. 93).

²⁵ Fort Knox is a fortress where the American Treasury stores its gold under double guard.

main function should be the balancing of international accounts. He writes:

... This is, in effect, what happens when foreigners pay us for excess exports in the form of gold. The gold is purchased by the Treasury and thus dollars are made available to foreigners with which to pay for the excess American exports. To be sure, the Treasury has obtained gold, but buried in Fort Knox it is of doubtful value. It is, of course, true that the Treasury can very neatly get out of its own difficulty by depositing the gold, or rather gold certificates or gold-certificate credits, with the Federal Reserve Banks, thereby receiving in return a balance at the Federal Reserve Banks. By so doing, the excess of American exports is financed not by the taxpayer but by an extension of Federal Reserve credit. It is, in fact, paid for by a multiplication of the money supply.

It is not to be wondered at that the gold purchase business, as a means of financing excess American exports, looks like hocus-pocus to many people. Some would prefer to go straight to the heart of the problem and finance excess American exports through an expansion of Federal Reserve credit without buying the gold and storing it away in Fort Knox. . . ."²⁶

Here Hansen actually develops his theory of deficit financing (or credit expansion) into a world law. Not only exports of goods, but export of capital as well, can be financed by expansion of credit. "The aggravation of the saving-investment problem can be avoided by deficit financing acting like a force pump on a world scale."²⁷ Hansen's position is perfectly clear: the creation of an international currency fund, with the United States playing the leading part, will, according to him, initiate such a "force pump" policy in which the United States, as the principal disbursing of world credits, will be the primary moving force.

But here Hansen prefers to hold his peace on two points: first of all, the huge reserves of world currency in the form of gold accumulated by the United States are not at all unimportant for that country, as the principal partner of the world currency fund. Secondly, the policy of a world "force pump" can become, and actually has already become, a method of subjecting other countries to political pressure in order to subjugate their economies to American monopolies.

With frankness and a cool head, the problem of United States world expansion is analysed by a professor of Washington University, George Taylor, whose sensational book *America in the "New" Pacific* published by the Institute of Pacific Relations has gone through five editions.²⁸ In Chapter VII eloquently entitled "Asia for Whom?" he writes:

America has to lead in the Pacific because that is what the war is about. There is no room in the Pacific for both the American and the Japanese type of expansion. Conflict with Japan was the logical result of a century of policy.

²⁶ Alvin H. Hansen, *America's Role in the World Economy* (New York, W. W. Norton, 1945), pp. 142-43.

²⁷ Translator's note: No page given, I re-translated this passage into English without checking.

²⁸ Mr. Ayzenshtadt evidently means five printings. The book was originally published in 1942.

Calling things by their proper names, Taylor lifts the curtain over the pre-war American policy in Asia:

In the XIXth century the policy of United States in Asia was directed towards strengthening Japan when Russia tended to become too powerful, and conversely, to support Russia when Japan gained strength, at the same time preventing too great a weakening of China. United States used its influence to prevent the growth of Russian and Japanese influence in Manchuria.²⁹

United States and Britain, says Taylor, aimed at "training Japan for the role of Asia's policeman."

With equal clarity, the ideologists of American imperialism also approach the Near and Middle Eastern problem. Elliot thinks that "the United States is the most remarkable country in the world, having accepted a 40 billion dollar lend-lease debt without any real prospects for its repayment."³⁰ As a compensation, he demands the participation of United States government in loans extended to other countries for productive purposes. This particularly refers to countries which are in the British "sphere of influence."

. . . There is, for example, no reason why we should not go into Iranian or Middle Eastern oil with our eyes open, if we go in at all, and ask for a definite governmental share as a method of underwriting loans. The British Government owns such shares now; and without our joint support this area, important as an oil area for both our navies and our airlines, may well be at the disposal of governments under other domination. United States should become the silent partner of the British Empire.³¹

Taylor goes further than Elliot. According to him, the United States should become more than a silent partner of the British Empire: it should replace it. In this process, the United States "will naturally lose its democratic appearance."³²

Taylor not only demands the liquidation of all remnants of democracy in the United States; he also presents a program for "the export of the ideas" of American imperialism.

According to him, "the United States is engaged, first of all in the . . . export of ideas. The concepts of family, Christianity, of individual rights—all these," says Taylor, "have revolutionized Asia."

The United States has exported its economic philosophy, according to which the whole of humanity (and first of all of course—the United States—A.A.) has a right to a free access to world supplies of raw materials . . . and also

²⁹ Translator's note: No page being given, I re-translated this passage without checking it.

³⁰ For source, see note 31. No page was given for the present quotation, and therefore I re-translated it without checking. Several sentences approximating its meaning can be found on pp. 196-97.

³¹ William G. Elliot, "An American Estimate of Britain's International Economic Position," *America's Place in the World Economy* (New York University, 1945), p. 197.

Translator's note: The last sentence does not appear in the original quotation, though the idea itself is expressed on p. 198.

³² Translator's note: No page given, I translated it without checking.

according to which the state derives the greatest benefit from free enterprise.

The "propelling forces" of this export of ideas are Christianity, Civilization and . . . Commerce, or the three C's.

Thus, the export of ideas is accompanied by the export of goods; Christianity plus Commerce, or more correctly, Christianity as one of the objects of commerce. Here Taylor finally does away with the garb of hypocrisy, and the true aim of American imperialism appears before us in its real light.

More than any other nation, the United States has relied in the Pacific on the power of ideas. . . . But at the same time it has made full use of American dollars as well as of American gunboats.³³

"Ideas" were thus implanted by means of dollars and gunboats. This confession fully illuminates the moving forces of American expansion. And Taylor frankly admits that "the penetration of United States into Asia is very far from the refinements of a drawing room story."³⁴

". . . The United States," says Taylor, "is an imperial power in the Pacific by virtue of the conquest of the Philippine Islands in 1898, the seizure of the Hawaiian Islands and such steppingstones as Midway, Wake, and Guam . . ." (p. 22).

The men, the institutions, the philanthropic and commercial dollars (Christianity and Commerce expressed in dollars.—A.A.) and the energy put into this expansion had an effect which cannot be measured exactly. It is not the number of Christian converts that matter. The fundamental point lies in the world expansion of American influence. . . .³⁵

It is impossible to portray American capitalism in a more naked form than that presented by its preacher Taylor.

Having rejected his democratic positions as if they were excess ballast, Taylor drops them on the way, and, with a "relieved soul and opened eyes," preaches the imperialistic expansion of the United States in the hope that this expansion will save capitalism.

The essence of all these "conceptions" lies in the preaching of an expansionist program for American imperialism. Therefore the exposure of the "ideology" of the adherents of American monopolistic capital is one of the necessary conditions for the peace and safety of peoples.

³³ The quotations in the text are my translations of Mr. Ayzenshtadt's paraphrases of Mr. Taylor's ideas expressed on pp. 22-25 of his book. To what extent Mr. Ayzenshtadt correctly interpreted Taylor's ideas, the reader can judge for himself.

³⁴ Translator's note: No page given.

³⁵ Translator's note: This paragraph, with the exception of the last sentence appears on p. 25 of Taylor's book. The last sentence is stated as follows: "It is not the number of Christian converts that matter, but the widespread acceptance of the American view of life."

COMMUNICATIONS

Professor Friedman's Proposal: A Comment*

Many economists will view sympathetically Professor Friedman's attempt to set forth long-run objectives of economic policy, fewer will look favorably upon the proposal suggested to him by these objectives, but many will quarrel with his analysis of the effects of this proposal.¹ Moreover, consideration of the "Implications of the Proposal if Prices are Flexible and Lags in Response Minor" (Section IV) suggests immediately the following question: what are the implications of flexible prices and frictionless economy in the absence of a "built-in" policy for stability such as that embodied in this proposal? Particularly, it seems questionable if, under such assumptions, his proposal would lead to progress toward the stated objectives beyond that of "discretionary action."

Friedman (p. 254) recognizes that one of the cornerstones for a rational economic program for a free enterprise system is price (including wage) flexibility. Admittedly price and wage rigidities destroy the virtue of the proposal and the "most that can be expected under such circumstances is a reasonably stable or moderately rising level of money income." This seems to me to be somewhat cold comfort. Although Friedman apparently feels that this maximum contribution in the face of price rigidity would have salutary effects on monopolistic practice and hence "make flexibility of prices a good deal easier to achieve," there is evidence to suggest that factors other than general deflation play a larger rôle as cause for such practices.² Furthermore, with rigidities present, and the virtues of the proposal largely non-existent, it is likely that policies not consistent with the proposal would be more effective. The illustration presented by Friedman of the effects of price rigidities (p. 253) in fact shows this to be the case. Assuming a stable economy, reasonably full employment, and wage rates rigid against downward pressure, then a rise in wages of any group requires a higher aggregate money income if employment is to remain stable. But his proposal at this point would bring forth a government surplus (receipts rise by more than

*The author is indebted to Miss Annette Weifenbach and Mrs. G. N. Conly of the Haynes Foundation for suggestions and criticisms during the preparation of this note.

² See G. J. Stigler, *The Theory of Price* (New York, 1946), pp. 198-201. Stigler suggests the desire for gain and the desire for power, neither necessarily cyclical in intensity, as the principal motives of monopoly. See also, F. C. Mills, *Price-Quantity Interactions in Business Cycles* (New York, 1946), p. 107. Mills finds price flexibility increasing as deflation progresses.

expenditures) which in turn forces a deflation the consequence of which can only be unemployment, since prices are assumed rigid. Friedman himself suggests the solution. "The only escape from this situation is to permit inflation" (p. 254), but for him there is no escape; discretionary monetary policy which might "permit" the required inflation is taboo. Price rigidities due to contractual arrangements, monopoly, or inertia are an inescapable element of economies for which fiscal and monetary policy must be designed. Price flexibility, even if it were achieved, would yield a full employment equilibrium only under "very special conditions," none of which would necessarily be created by the several elements of Friedman's proposal.³ Thus, policy, to be effective, must at best be designed to contribute substantially to stability in economies in which price rigidities exist, and must at least not be completely ineffective in the face of rigidities.

There is virtue, however, in knowledge of the process by which monetary and fiscal devices bring about results, even though the conditions assumed are heroic. Perhaps knowledge of this process in a simplified setting is a necessary first step in understanding the effects of these devices in the real world, one in which frictions and price rigidities are significant. But Friedman's investigation of the implications of his proposal assuming flexible prices and minor lags contains errors so important that the virtue of his analysis is lost.

According to this analysis, the fundamental correctives for a decline in aggregate demand "are (1) a decline in the general level of prices which affects (a) the real value of the community's assets and (b) the government contribution to the income stream, and (2) an increase in the stock of money" (p. 259). Price decline following a fall in aggregate demand, according to Friedman, will increase the real value of the community's assets, hence increase the propensity to consume, and therefore increase aggregate demand. His faith in this force is sufficiently strong to justify the statement that this force "would alone be sufficient to assure full employment. . . ." But the propensity to consume is not sufficiently sensitive to holdings of real assets to make the required response come about; furthermore, there is evidence that the effects of price decline on expectations is such that the consumption function is adversely affected.⁴

Friedman's second fundamental corrective, an increase in the stock of money, originates from the government deficit created and the fact that the

³ Cf. Oscar Lange, *Price Flexibility and Employment* (Bloomington, Indiana, 1944), pp. 83-85. The consequences of perfect price flexibility on the level of employment provides the basis for much of the controversy between the disciples of Lord Keynes and economists of classical persuasion. The former vigorously deny that perfectly flexible prices will guarantee full employment. The latter have varying degrees of confidence in price flexibility, depending on the extent of the Keynesian "taint." An interesting and thorough discussion of this controversy is to be found in a recent article by Don Patinkin, "Price Flexibility and Full Employment," *Am. Econ. Rev.*, September, 1948, pp. 543-64.

⁴ Cf. Patinkin, *op. cit.*, p. 554, note 19, pp. 557, 558; and Lawrence Klein, "The Use of Econometric Models as a Guide to Economic Policy," *Econometrica*, Vol. XV, pp. 122-25.

proposal requires that the deficit be financed by the issue of money. This increase is assumed first to raise the average propensity to consume in the same manner as price decline raises it (by increasing the value of real assets) and, therefore, to raise prices and aggregate demand until a full employment equilibrium is reached, at which time the deficit ceases to exist and no further increments to the money stock occur. As indicated above, it is doubtful if the propensity to consume will react so as to bring about the results Friedman assumes. In this case, however, there is somewhat more hope that it will, for expectations are unlikely to be severely damaged, but the fact remains that the effect on saving of changes in the value of assets is likely to be small. The proposal precludes increases in the stock of money beyond that created by the automatic deficit. Sharp discretionary increases in money are proscribed. The proposal provides a sop to the more vigorous deficit spenders, but rigidly limits the extent to which the policy may be carried. The process of recovery is based not upon direct increments to aggregate demand resulting from government investment; rather it is based upon the hope (probably vain) that the propensity to consume will increase.

If, however, we make the assumption that there is a direct relation between the propensity to consume and the real value of assets (a questionable assumption at best, but one necessary to Friedman's argument), there is still considerable doubt about the manner in which the anticipated outcome is brought about. Friedman's position, as stated on pages 259-61, is that either falling prices or constant prices and an increased stock of money will increase the real value of assets, hence the propensity to consume and hence aggregate demand.

A decrease in prices (increase in the real value of assets) must be sufficient to raise the consumption function; the magnitude of the adjustment required depends upon the extent to which aggregate demand is deficient. Falling prices may so damage expectations that any rise in the consumption function is offset by decreased investment. In other words, the increase in the propensity to consume would have to be the greater the more responsive investment is to decreasing prices. And, as prices fall, the favorable effect upon consumption will ultimately tend to grow progressively weaker. Some individuals (the rich) will not be induced by increasing real asset values to spend larger proportions of their incomes on consumption. Rather, they will save more. Others, of course, will increase this proportion but increases in the average propensity to consume due to the shifts in their spending habits are limited. Thus, the deflation may have to be extreme before the net effect upon aggregate demand is sufficient to restore a high employment equilibrium.

Friedman's second fundamental corrective appears, on the other hand, to offer somewhat more comfort, but for reasons other than those he suggests. An increase in the money stock also will increase the real value of assets, and to the extent that this pushes the consumption function upward it will, it is true, cause aggregate demand to react favorably. In this instance, the decline in prices need not necessarily exceed that associated with the original decline in aggregate demand. But since the increase in the money stock is limited by the extent of the deficit, further price decrease may be essential if the in-

crease in real asset values is to drive the consumption function upward. Moderate price decline is unlikely to depress investment as much as precipitate decline. If, after the initial deflation, the increased money stock is alone sufficient to lift consumption, then investment may increase and itself assume the principal rôle in restoring full employment. It is this possibility, that investment will increase, which makes Friedman's second fundamental corrective slightly more palatable than his first; yet, he apparently prefers to disregard it.

Thus, even granting Friedman's necessary assumption (that the consumption function and real asset values are directly related), the mechanism by which a favorable equilibrium is restored is considerably more complex than that described in "Framework for Economic Stability." Adjustments required when discretionary action is foresworn may be extreme, so extreme that the proposal will provide instead a rigid framework for instability. It seems apparent that this proposal for "built-in flexibility" requires such unique reactions that it could not (even in a flexible price world) be relied upon to do the job alone; even there discretionary counter-cyclical policy is necessary. In a world of rigidities and frictions such policy is even more essential.

PHILIP NEFF

The Haynes Foundation and The University of California at Los Angeles

Rejoinder

The central feature of the monetary and fiscal framework for economic stability outlined in the article criticized by Dr. Neff is that it dispenses as much as possible with discretionary action and relies almost entirely on automatic reactions. While Neff does not discuss explicitly the relative merits of automatic and discretionary action—of "rules" *vs.* "authorities"¹—it is clear that this is the basic issue between us. To Neff, "even in a flexible price world . . . discretionary counter-cyclical policy is necessary. In a world of rigidities and frictions such policy is even more essential."

I shall first comment on this basic issue and then turn to Neff's explicit criticisms: (1) that "admittedly price and wage rigidities destroy the virtue of the proposal"; (2) that my analysis of the proposal "assuming flexible prices and minor lags contains errors so important that the virtue of [the] analysis is lost."

1. *Alternative Stabilization Policies*

Neff does not argue that the automatic reactions under the framework I outlined will have effects that are in the wrong direction, but rather that they

¹ Henry C. Simons, "Rules versus Authorities in Monetary Policy," *Jour. Pol. Econ.*, Vol. XLIV, No. 1 (Feb., 1936), pp. 1-30; reprinted in Henry C. Simons, *Economic Policy for a Free Society* (University of Chicago Press, Chicago, 1948), pp. 160-83. It should be noted that Simons emphasizes the political implications of rules versus authorities and not merely their relative effectiveness. The restriction of the comments below to the latter question does not reflect any doubt about the virtues of "rules" in preserving political democracy; it is occasioned rather by the irrelevance of the political issue to the present discussion.

"could not be relied upon to do the job alone." This criticism makes sense only if alternative or supplementary discretionary policies are known that are reasonably certain to temper instability more effectively than the automatic reactions alone. Yet Neff does not even state explicitly what policies he favors, let alone establish a case that they would be more effective. Can it, then, be taken for granted that the addition of unstated and undefined discretionary action will necessarily improve matters?

The contention that this can be taken for granted is typically defended somewhat as follows: You admit that your "proposal may not succeed in reducing cyclical fluctuations to tolerable proportions," that "the forces making for cyclical fluctuations may be so stubborn and strong that the kind of automatic adaptations contained in the proposal are insufficient to offset them to a tolerable degree" (my article, p. 264). Why, then, not simply add discretionary action to the automatic reactions so as to be ready for all eventualities? After all, a discretionary authority can certainly do at least as well as your "rule," since, if it thought that the "rule" would work, it could refrain from taking any action or make its action identical with that which the "rule" would produce. If it took any additional action, it would be because the rule wasn't working well, so that the additional action could be presumed to improve matters.

Despite its plausibility, this argument is fundamentally fallacious. In the first place, even if the authority could and would do exactly what the "rule" prescribed, the results might well be very different. A "rule" gives the community a different basis for predicting the reactions that will take place than an "authority" does. Thus the same actions will be attended with a different degree of uncertainty, and I should argue more uncertainty, if carried out by an authority than if the result of a "rule," thereby changing the cyclical forces to be countered.

In the second place, it is not clear that an authority could follow the "rule" even if it thought it desirable to do so. It would be subject to political pressures, and affected by the general climate of opinion. To be successful, the authority must take action largely counter to that being taken by the rest of the community. Can it have the independence of mind and strength of character to do so? If it does, can it remain in power? Our experience along these lines should make us anything but sanguine. The Federal Reserve System has operated under highly advantageous circumstances, yet I think it likely that on balance its discretionary action has been destabilizing, the most striking example being the sharp deflationary action it took in the fall of 1931.

It may be replied that the political pressures that would prevent an authority from operating successfully would prevent adoption of the "rule." This may be, but the first amendment to the Constitution offers an instructive example of the possibility that the community may favor a self-denying ordinance proscribing a bundle of actions most or all of which, taken separately, it would favor.

In the third place, it is not obvious that additional discretionary action would improve matters even though the authority were completely free from political pressure. There is no more egregious fallacy than the belief that a

series of counter-cyclical actions will on balance be stabilizing if only they are in the "right" direction more frequently than in the "wrong" direction; stated differently, that an authority will do harm only if its actions are perverse. On the contrary, a series of actions, most of which are in the "right" direction, may still intensify cyclical fluctuations rather than reduce them.² Further, as I argued at some length in the article under discussion (pp. 254-58), circumstances that would make the automatic reactions I described work poorly or be destabilizing would be extremely likely to make discretionary actions of the kind so far proposed work even worse or be even more highly destabilizing.

We do not have an acceptable theory of cyclical fluctuations or of the causal forces at work. But it is clear that lags in response play an essential rôle in the generation and propagation of cyclical movements. And it is precisely these lags that render uncertain the effectiveness of counter-cyclical action. Yet the presumption that discretionary counter-cyclical action will be predominantly or overwhelmingly in the "right" direction is implicitly premised either on negligible lags or on an ability, which we clearly do not have, to forecast future movements in aggregate demand.

These implicit assumptions perhaps explain why most proposals for discretionary counter-cyclical action specify explicitly neither the location of authority for action, nor the criteria on the basis of which action is to be taken, nor the precise action to be taken. If reasonably concrete specification of these essential features of the proposals were attempted, I believe that the present appearance of widespread agreement on discretionary counter-cyclical policy would dissolve into thin air. The agreement is on objectives, not on a reasoned proposal for social action.

2. Price Flexibility

Both Neff's comments and those made by others suggest that my article can be justly criticized for not dealing explicitly with the "excluded middle" between "perfect flexibility" of prices, including wages, and complete rigidity, at least against declines. To bring out starkly the rôle of price flexibility, I analyzed in detail the two extreme cases, though I did mention in a footnote that the effectiveness of the proposal did not depend on "'perfect' flexibility of prices, however that might be defined" (my article, p. 258). Neff applies the analysis of what I designated "an extreme example" directly to the real world, accepts my conclusion that "the only escape from this situation [the extreme example] is to permit inflation" (my article, p. 254), and proceeds to recommend that

² See Milton Friedman, "Lerner on the Economics of Control," *Jour. Pol. Econ.*, Vol. LV, No. 5 (Oct., 1947), p. 414, especially footnote 12.

The fundamental point is contained in the statistical theorem that the variance of a sum of two components is the sum of the variances plus twice the covariance. A negative covariance is thus not enough to insure that the variance of the sum is less than the variance of one component; in addition, the covariance must exceed in absolute value one-half the variance of the other component. In connection with the present problem, one component may be taken to be the aggregate demand in the absence of the counter-cyclical action contemplated; the other component, the addition to or subtraction from aggregate demand attributable to the counter-cyclical action.

inflation be permitted. Having gone so far, he should have gone farther and inquired whether even inflation would be a permanent "solution." Would it not have to become cumulative to remain a solution? Would not the resultant inequities and disruptive economic effects lead the community to prefer considerable unemployment to continued inflation?

Reality, of course, corresponds to neither extreme. At most, "many prices are moderately rigid, at least against declines" (my article, p. 253). Under such circumstances, the virtues of the proposal are not destroyed; the proposal will work better than under extreme rigidity, less well than under extreme flexibility. With a moderate degree of rigidity, "a reasonably stable or moderately rising level of money income" would be an eminently satisfactory outcome.

In the present state of our knowledge—or ignorance—reasonable men can hold widely different judgments about the quantitative importance of price rigidity. My own judgment is that there is more danger of exaggerating than of understating its importance. Further reflection and observation of the course of events have led me to attach even less importance to rigidity than I did when I wrote the article. Given a substantial segment of reasonably flexible wages and commodity prices, the fact that other commodity prices and wages are rigid will increase the average level of "frictional" unemployment; but is unlikely to be a serious obstacle to the effective operation of the proposal. Casual observation is particularly treacherous on a point like this. One tends to neglect devices invented to circumvent apparent rigidities. Moreover, rigidity is far more newsworthy than flexibility; it leads to consequences that command attention. We hardly ever realize that the price system is operating except when its operations are interfered with.

3. Analysis of the Implications of the Proposal

The section of my article that Neff characterizes as containing "errors so important" as to destroy the virtue of the analysis does not pretend to be an exhaustive analysis of cyclical forces. It is explicitly restricted to describing the "stabilizing economic forces" on which the "ideal possibilities of the monetary and fiscal framework proposed . . . depend" (my article, p. 258). It thus neglects forces not directly connected with the monetary and fiscal framework (e.g., "changes in relative prices and interest rates," my article p. 259), and only mentions by way of qualification such factors as "the number and magnitude of the disturbances to which the economy is subject, the speed with which the equilibrating forces operate, and the importance of such disequilibrating forces as adverse price expectations" (my article, p. 261-62).

The chief conclusion of this analysis is that there are four main automatic reactions that would come into play to counteract changes in aggregate demand: [1] "the adjustment of transfer payments and tax receipts to changes in employment. This eases the shock while the defense is taken over by changes in prices. [2] These raise or lower the real value of the community's assets and thereby raise or lower the fraction of income consumed. [3] They also produce a government deficit or surplus in addition to the initial deficit or surplus resulting from the effect of changes in employment on transfer pay-

ments and tax receipts. The final line of defense is [4] the cumulative effect of the deficits or surpluses on the stock of money. These changes in the stock of money tend to restore prices to their initial level." (My article p. 261, numbers in brackets added.) I called (1) a "shock absorber" and (2), (3), and (4) the "more fundamental correctives" because (1) alone can at best offset only part of the decline in real aggregate demand and is in operation only so long as there is unemployment, whereas the remaining forces are not so limited.

Neff's criticism of this analysis is marred by a serious error of omission. He does not even mention (1), and he completely neglects (3). Thus he comments, "The process of recovery is based not upon direct increments to aggregate demand resulting from government investment; rather it is based upon the hope (probably vain) that the propensity to consume will increase." But forces (1) and (3) are analytically equivalent to "direct increments to aggregate demand" and their operation is entirely independent of any effect of changes in the real value of assets on the propensity to consume.

The omission of (1) is particularly regrettable. The federal fiscal system now has vastly greater "built-in flexibility" than before the war, largely as a result of the increased importance of the income tax and the changed technique of tax collection. Indeed, I believe this is by far the most important change in recent years in the economic environment relevant to stabilization policy. Estimates by Musgrave and Miller, as well as other evidence, suggest that force (1) alone is likely to offset something like a quarter or a third of any change in aggregate demand.³

As nearly as I can tell, the positive errors of which Neff accuses me are (a) that I suppose the average propensity to consume to be positively related to the real value of the community's assets—or perhaps that I suppose this relation to be quantitatively more important than it is; (b) that I neglect or understate the effects of adverse price expectations; (c) that I take no account of indirect effects on investment, apparently themselves largely to be explained by adverse price expectations.

a. It is not clear whether Neff denies that, other things the same, a rise in the real value of the community's assets will raise the average propensity to consume. In any event, he argues that the "propensity to consume is not sufficiently sensitive to holdings of real assets." I do not see how either the existence or direction of the effect can be denied. As indirect evidence of its importance, I would cite the relative secular stability of the propensity to consume, and the apparent absence of strikingly wide differences between rich and poor countries in the propensity to consume. The effect in question seems to me one of the major explanations of both phenomena. But this is evidence for a secular effect, not for a relation over short periods. Empirical evidence on the short-period relation is almost completely absent. Additional work on this problem is urgently needed. Suppose, however, that a reasonably accurate estimate of the magnitude of the effect were available. How large

³ R. A. Musgrave and M. H. Miller, "Built-in Flexibility," this *Review*, (Mar. 1948), pp. 122-28. As was pointed out in my article (footnote 20a, p. 261), force (1) is the only one taken into account by Musgrave and Miller.

an effect would make the propensity to consume "sufficiently sensitive"? On this point, I believe that Neff's neglect of forces (1) and (3) leads him to overstate the "sensitivity" that in some sense is "sufficient."

b. When a decline in aggregate demand sets in, prices tend to decline. Neff argues that this decline in prices will lead to expectations of further price decline, and that these adverse price expectations will cause consumers to reduce their consumption, and business enterprises to reduce investment, thereby offsetting, or more than offsetting, any favorable effects of the price decline on the propensity to consume *via* its effect on the real value of the community's assets.

This possibility cannot be denied and, as noted above, was explicitly recognized in my article. Here again the question is empirical. How likely are price expectations on balance to be favorable rather than adverse? If adverse, how large will their destabilizing effect be? My judgment on this point is very different from Neff's. I should argue that price expectations may be expected to be largely stabilizing or neutral in the early stages of either a decline or rise in prices, and to become strongly adverse only at a considerably later stage when the decline or rise has degenerated into a drastic deflation or inflation. The behavior of the velocity of circulation in the earlier stages of all great inflations of history and our experience in two world wars seems to me to lend strong support to this view. But it may be argued that there is asymmetry between rises and declines in prices, that rises are generally expected to be reversed, but declines to continue. There is less evidence for declines than for rises, but I should argue that our experience in 1929-31 and, indeed, in most contractions, supports, or, at least, does not contradict, the view expressed.

The prevalence of the view held by Neff is to be explained, I think, by concentration on dramatic cases such as 1931-33 and the later stages of great inflations and by the temptation to think in terms of drastic rather than gradual price movements. I doubt that 1931-33 can be explained as a direct consequence of adverse price expectations. It is better explained, in my view, by the inappropriate action of the Federal Reserve System in the fall of 1931, which in turn led to adverse price expectations and other cumulative forces that rendered the subsequent reversal of Reserve policy ineffective. "*Natura non facit saltum*" applies to changes in aggregate demand as well as to other economic changes. Surely, the typical case for which counter-cyclical policy should be designed is a gradual decline or rise in aggregate demand, in which case discontinuous changes in expectations are hardly to be expected.

Finally, the existence of a stable monetary and fiscal framework will itself be a factor tending to stabilize expectations. In view of the historic instability of monetary and fiscal forces, particularly monetary, the surprising thing is that expectations have not in the past been even more destabilizing.

c. In so far as Neff's dissatisfaction with my treatment of investment reflects more than a difference between us on the importance of adverse price expectations, I suspect that it arises out of my failure to specify the source of the initial decline in aggregate demand that I assume to get the analysis going and my failure subsequently to mention explicitly changes in consumption or in investment other than those arising directly from the operation of the stabilizing forces.

It clearly makes no difference whether the initial decline in aggregate demand arises from an autonomous decline in consumption or in investment; in either case, the effect is identical. Subsequent induced changes involved in the so-called "multiplier" effect are implicitly taken into account in my analysis (see the second paragraph of footnote 19 on page 260 of my article and the accompanying text). Further changes are irrelevant to the argument. They are in effect included in "the disturbances to which the economy is subject." They affect the destabilizing forces which automatic reactions must counter, but not the operation of the automatic reactions themselves.

MILTON FRIEDMAN

University of Chicago

Final Comment

My difference with Professor Friedman is not based upon the belief that all fiscal and monetary policy should be discretionary, that "authority" is to be preferred over "rule" in every instance. Indeed it would be as impossible to establish a monetary and fiscal system completely devoid of "rules" as to provide ironclad guarantees against any future discretionary action. I feel rather that some discretionary action will be required, particularly in view of price rigidities and volatile expectations. Friedman, in his rejoinder, considers the central feature of his proposal to be the fact that "it dispenses *as much as possible* with discretionary action and relies *almost* (my italics) solely on automatic reactions." Thus both of us apparently believe that discretionary action will have a significant rôle to play, in spite of the virtues of a logical fiscal and monetary system.

The supplementary discretionary policies called for by the failure of the economy automatically to right itself are several. Friedman himself (pp. 253-54) describes deflationary conditions which monetary inflation would correct, while the contribution which may be expected from a discretionary government investment program has been the subject of extensive literature over the last decade and a half. It is possible that Friedman and I would disagree on what particular action would be appropriate to given circumstances but his suggestion in the rejoinder, "that to be successful the authority must take action largely counter to that being taken by the rest of the community," leads me to believe that even on this we would not be far apart.

Friedman and I agree that price rigidities and lags complicate counter cycle policies, but disagree with respect to their significance. I hold that whenever price rigidities defeat automatic adjustments, whether these adjustments be those resulting from Friedman's proposal or those that are now inherent in the system, discretionary action can provide some contribution to fuller employment. That lags will reduce the efficiency of either automatic or discretionary action is quite clear, but Friedman's belief that his proposal minimizes lags is not convincing. Surely the change in variables that brings his "correctives" into operation could be relied upon as a guide for policy.

In my earlier reply to Friedman's article I failed to comment on his correctives (1) and (3) because they already operate in our system, and although I appraise their strength somewhat less than some economists, I wel-

come their existence. Though these correctives have not in the past been sufficient to head off every contraction, it would be nonsense to deny them some salutary effect. My argument represents an attempt to show (contrary to Friedman) that correctives (2) and (4) could not be relied upon to do the job alone, for the favorable effects, unfortunately, are accompanied by unfavorable ones. Obviously, the success of any program for built-in flexibility depends upon the job to be done. If correctives (1) and (3) are sufficient, then no sensitivity of the propensity to consume to real asset holdings is required. But if contraction continues, a high degree of sensitivity is essential if Friedman's proposal is to operate successfully. Evidence concerning its sensitivity is fragmentary, but I believe that "the secular stability of the propensity to consume, and the apparent absence of strikingly wide differences between rich and poor countries in the propensity to consume" supports my position, not Friedman's. Moreover, if a deflationary movement is sufficiently mild that price expectations are favorable, then certainly the required sensitivity of the propensity to consume is less than in periods of contraction sufficiently sharp to create adverse price expectations.

PHILIP NEFF

Hungary's Monetary Crisis: Comment

In the September, 1948, issue of the *American Economic Review*, Professor Nogaro published a very interesting paper under the title "Hungary's Monetary Crisis and its Theoretical Meaning." Unfortunately, some errors can be found both among his statements of fact and the conclusions he arrives at, which I should like to correct.

First of all, what Professor Nogaro says about the motives that led to the introduction of the tax-pengő needs amplification. According to him "The tax-pengő's creation was quite empirical; it did not follow from any pre-conceived ideas. Its purpose was to guarantee tax revenues" (p. 539).

This is not the whole truth. The reason for introducing the tax-pengő as money of account was to enable the National Bank through the valorization of credits to grant credits justified both on general grounds and in the particular case and, at the same time, to prevent the firms from making profits out of the depreciation of the currency brought about by the inflation which at that stage was considered to be unavoidable. The war destroyed the real working capital of the firms while the inflation destroyed their monetary capital. Restarting production was impossible without providing credits, for wages had to be paid. The reparation deliveries require special consideration. A large part of the reparation goods consisted of machinery requiring long production periods. To finance their production, credits or advances were necessary. Accounts could be settled, of course, only after the delivery of the goods and it seemed just that the credits and advances granted should be valorized in one way or another lest the firms should make inordinate profits. Apart from that, many firms required credit to restore the productive capacity of their war-damaged plant. The government thought that the

bank of issue should provide these credits without, however, letting the firms make inordinate profits.

It was to be hoped that the valorization of the commercial credits by means of the tax-pengő would ensure the reflow of at least part of the great quantity of money issued in the course of the inflation. If on January 1, 1946, the date of the introduction of the tax-pengő, when 1 tax-pengő was equal to 1 paper-pengő, somebody contracted a short-term credit of 1 million pengős on the condition that after three months he would have to pay back as many times more paper-pengős as it had been necessary to issue in consequence of the inflation, the repayment of the larger amount of paper-pengő would, it was thought, to some extent counterbalance the effects of the inflation.

Another motive was, and Professor Nogaro is right in pointing this out, to valorize tax-receipts, not only the direct taxes but also the indirect taxes, amongst them the purchase taxes fixed in percentage of the prices of goods.

It seems to me that the scheme broke down for four reasons:

1. At the time of the introduction of the tax-pengő, the volume of credits was extremely small and did not by any means correspond to the real needs of economic life. For the reasons given above credits had to be granted in an increasing volume but when due were not repaid but prolonged. Thus the expected reflow of money never took place.

2. The national economic budget lacked equilibrium. Professor Nogaro does not seem to be aware of the importance of the economic budget when in the section "A New Conception of Inflation" (p. 534) he is puzzled how the sum total of the money incomes could have surpassed the aggregate money value of the goods and services available. Although he does not say so, he must have been thinking in terms of the concepts of the market theory of Jean Baptiste Say, according to which the total value of output included the incomes of all those who had been instrumental in producing it. This conception is valid only if two conditions are fulfilled: (a) The sales price of every commodity is greater than its cost price; (b) The people in receipt of salaries and wages want to buy the goods that have been produced.

We may add as a third condition that the balance of the budget is achieved by ordinary means, *i.e.*, without recourse to an inflation.

After the war none of these conditions was fulfilled in Hungary. The sales price of many a commodity was fixed below the cost price out of social considerations. This did not mean that the firms producing them were working at a loss because to bridge the gap they contracted credits which melted away in the inflation. At the same time, as mentioned above, they profited in carrying out an investment program with the help of inflated credits. Economic equilibrium suffered even more from the fact that the purchasing power distributed in the form of salaries and wages created a demand for goods which at that time were not available. The recipients of incomes wanted consumer's goods, the quantity of which was not sufficient. A larger part of the social product was made up of producers' goods than was warranted by the volume of savings, the more so because owing to the low in-

come level the propensity to save was practically nil and the volume of savings hardly exceeded the enforced savings of the inflation. This period offered a striking illustration of the wage-fund theory: If the recipients of incomes refuse to save, their aggregate real income cannot exceed the available quantity of consumers goods.

3. The investments of the inflation period were greater than what the equilibrium of the national economic budget allowed. The inflation was therefore inevitable. However, the capital accumulation made possible by a rapid inflation led to the speedy reconstruction of plant. Had it not been for that, the subsequent rise of the national income would not have been as marked as it was.

In 1945-46 the composition of the social product could not be changed because there was no possibility of increasing the quantity of consumers goods. Before gathering in the harvest of 1946 the stocks of food and raw materials could not be increased. Neither was it possible to replenish them through imports in exchange for capital goods because these were needed at home to make the future extension of the production of consumers goods possible and because no consumers goods were available in other European countries.

4. There were also technical mistakes which speeded up the process of depreciation. For example, the fixing of the prices and wages in tax-pengő increased the volume of money that was necessary. The equilibrium of the national economic budget was not ensured in tax-pengő either. The sum total of the claims against the social product was, even if expressed in tax-pengős, greater than the total value of the consumers goods expressed in—by definition stable—tax-pengő. For the reasons given above this must have led of necessity to an inflation of the tax-pengő which, in its turn, speeded up the inflation of the paper-pengő. Later, the inflationary process was speeded up because the value of the tax-pengő expressed in paper-pengős did not measure exactly the actual depreciation of the paper-pengő, owing to the inevitable time lag. The prices which served as the basis of the computation were always the prices of the previous day and that led to a great difference between the legal and the real value of the tax-pengő. This fact was duly discounted by the market and led to speculative price increases. There was also an inevitable time lag between the inflow and outflow of money in the Treasury and thus, in spite of the valorization of the tax-pengő, the revenue collected in paper-pengős was much below what was needed. Finally, there was also the technical flaw referred to by Professor Nogaro, *i.e.*, that private individuals were able to defend themselves against the depreciation of the paper-pengő by putting their paper-pengős into the bank in the evening on the basis of the lower quotation of the tax-pengő of that day and drawing on their account a larger sum on the basis of the higher quotation next day.

In consequence, the valorization of the credits and the tax receipts proved to be a failure. But even if the experiment of the tax-pengő was unsuccessful, it cannot be denied that in other spheres Hungarian economic policy followed a clear and consequential line and that its consequentiality bore fruit.

Several phases can be distinguished in the economic policy of the postwar period.

1. In 1945-46, at the time of the inflation, the aim was the speedy reconstruction of plant. Even the land reform carried out in the Spring of 1945 had that aim. Appeal had to be made to the enthusiasm of the new owners to till the land that had become their own, even without the necessary number of farm animals and other equipment, and prepare the way to a bigger crop in 1946. With the large estates intact this would hardly have been possible because the landlords lost the necessary authority for the running of large farms and, in any case, would not have been able to pay their labourers and provide them with food. Although the formula used was different, the principle applied was essentially the same in manufacturing industry. The aim was the speedy restoration of the productive capacity of plant even if that required the pressing down of real earnings to a very low level.

2. On August 1, 1946, a new currency was introduced and a new pattern of income distribution was set up by decree. Salaries and wages were fixed not in proportion to the levels that prevailed at the end of the inflation period but on the basis of purely theoretical considerations. The same applied to the fixing of taxes and to the drawing up of the investment program of the State. The basis of the plan was a national economic budget which showed an equilibrium not only in its grand totals but also in details, in production and demand in individual sectors. The level of wages was raised considerably corresponding to the increase in the volume of consumers goods. The prices of manufactured goods were fixed below costs, the assumption being that the increase of the level of real earnings would bring the productivity of the workers to a level where the losses of the industry would be eliminated. The gamble was bold but was successful. While 1945-46, the first year following the war, served the reconstruction of plant, 1946-47, the first year of the currency reform, served the increase of real income.

3. In the Three-Year Plan launched on August 1, 1947, the two aims appear in combination. It is intended to increase the capacity of plant and the standard of living simultaneously.

In addition to these comments I should like to rectify some errors which crept into statements of fact.

The depreciated pengő of 1938 was made equal to 2.29 forints and not to 2.07 forints. But as the gold value of the 1938 pengő was fixed in fact but not in law, it must be mentioned that the gold value of the pengő introduced on January 1, 1927 was 3.5 times greater than that of the forint.

According to a statement on page 526, 828 octillion (1 octillion = 10^{27}) depreciated pengős were equal to 1 prewar pengő. The statement is erroneous partly because the parity was fixed in a way different from what Professor Nugent assumed and partly because the change-over from the depreciated pengő to the forint was an arbitrary action. It is wrong to try to establish the rate of the depreciation of the pengő at the end of the inflation backwards from the value of the forint. The only true measure is the purchasing power. Applying that, we find that the commodity value of 1 pengő in 1938

was about equal to that of 1.4 nonillion (10^{30}) depreciated pengő in July, 1946.

On page 532 Professor Nogaro says that rents were fixed at 60 and 40 per cent, respectively, depending on the highness of the rent. In fact, the 40 per cent level was the one adopted and that had to be multiplied by 3 to arrive at the forint rent whereas the multiplier used in the case of prices was in general over 4. Thus the level of rents is below 30 per cent. Exceptionally higher rents are being paid for large flats but the greatest part of the difference is collected by the Treasury in the form of a tax.

STEPHEN VARGA*

*The author is professor of economics and statistics at the University of Budapest, Hungary, and president of the Hungarian Institute for Economic Research.

Hungary's Monetary Crisis: Rejoinder

I have read with much interest Professor Varga's comment. It is a useful addition to the data which I have been able to gather from the documents available to me and especially from his own article in the *Neue Zürcher Zeitung*.

I note with satisfaction that the "errors of fact and of interpretation" which he mentions are quite few, that they refer to relatively unimportant details and that they do not change my conclusions.

Professor Varga questions whether the creation of the tax-pengő was entirely empirical. He points out that its creation also answered the need for opening credit accounts to businessmen without permitting them to repay these advances by a currency which had lost a great deal of its purchasing power between the time of the loan and the time of repayment.

I was quite aware of this use of the tax-pengő, but some of my sources indicated that its creation was entirely empirical and had not originally had this purpose. I therefore acknowledge Professor Varga's interpretation.

As to the figures which I mentioned in connection with the depreciation of the pengő, I calculated them exactly on the basis of the data which were available to me. Professor Varga explains that the depreciated pengő of 1938 was equal to 2.29 forint and not to 2.07 forint, the figure which I used. Again, I defer to his views. Furthermore, I know as well as he that the only standard which can be employed in comparing effectively the value of the two monies, is their purchasing power.

BERTRAND NOGARO

Inflation and Equality: Comment

In the December, 1948 issue of this *Review*, Professor David McCord Wright concludes (although in the form of a question) that, in order to meet the threat of secular inflation, we need "(1) less taxation of profits, (2) less progressive taxation, (3) higher interest rates."¹ Both (1) and (2) mean a redistribution of the tax burden in favor of the rich and against

¹ D. M. Wright, "Inflation and Equality," *Am. Econ. Rev.*, Vol. XXXVIII, No. 5 (Dec., 1948), p. 896.

the middle- and lower-income groups. The argument of this comment is, first, that it is misleading to argue that tax reductions on high incomes are necessary "in order to increase saving"; second, that if the objective is to increase investment, there may be other ways to do it, more acceptable to the egalitarian ideas that some of us possess; third, that there exists no obvious case on welfare grounds why inflation should be curbed primarily by reducing consumption rather than investment.

Professor Wright holds, first, that inflation rather than unemployment seems to be our secular outlook for "about 25 years." For the sake of argument let us accept this. Now inflation means that the real spending desires of consumers, investors, and government exceed the real capacity of the economy to produce. Hence, if inflation is to be avoided, the sum of such expenditure desires must be reduced. As between reducing consumption and reducing investment, Wright chooses consumption. To say that consumption plus investment expenditures tend to outrun capacity production is equivalent to saying that investment tends to outrun saving. This way of putting it, however, is not well adapted to sound analysis of some aspects of the problem, since it tempts us toward fallacious reasoning of the sort that follows. If we don't want to reduce investment, then we must increase saving. What groups do most of the saving? The high income groups. How do we get them to increase their saving? Let them retain more income, by reducing their taxes. Despite the poor family mentioned in *Fortune* who were barely "getting along" on \$25,000, both Wright and I believe that the rich have a marginal propensity to save greater than zero—appreciably greater, I'd say. Hence, more disposable income, more saving. The way to solve our problem is to increase the disposable income of the rich.

Now I am sure that Wright realizes the fallacy in the argument as I have stated it, but some others who talk this way don't, and Wright's argument is not well calculated to disillusion them. *Reductio ad absurdum*: even the poor have a marginal propensity to save at least slightly greater than zero. Hence we could get *still more saving* by reducing their taxes, too. The trouble is, of course, that if you increase disposable income by tax reduction you do increase saving, but you also increase consumption, and add to rather than subtract from the inflationary pressures. The problem of inflation control is not to increase saving, but to reduce consumption. It is misleading to argue that we need to reduce taxes on the rich "in order to increase saving" and thus control inflation.²

It is obvious, of course, that if a *given* total amount of taxes is to be collected, taxing the poor reduces consumption somewhat more than taxing the rich.³ I see little reason, however, why we need to think in terms of a

² The same fallacy is involved in the depression argument that we should "soak the rich" because they save too much. Although Wright repeats this prescription, it too is wrong. "Soaking the rich" reduces their consumption (as well as their saving) and is, by itself, deflationary.

³ Although the conclusion of Musgrave and Painter ("The Impact of Alternative Tax Structures on Personal Consumption and Saving," *Quarterly Journal of Economics*, August, 1948) is that redistribution of the tax burden cannot have important effects either way.

given total amount of tax collection. It is likewise clear that taxation heavy enough to exert control over recent inflationary pressures cannot be confined to the rich—there are simply not enough of them, and their total consumption is too small. I take these facts for granted, and assert that they are not particularly relevant to Wright's argument. If the problem is to avoid inflation, without reducing investment, then we must reduce consumption, and it doesn't much matter whose. If there is fear that additional taxation of high incomes might reduce attempted investment, why is Wright not content merely with additional taxes "on the ordinary citizen"? Why must we *reduce* taxes on the high incomes, as is clearly suggested at several points?

Is this merely because inequality is desired on other grounds? Professor Wright has argued elsewhere, and very ably, the case for inequality.⁴ Although I cannot fully accept his conclusions, I recognize the difference as largely one over *values*. My objection here is only to the necessary association of the question of equality with that of inflation control. Avoiding inflation without reducing investment does not call for reducing taxes on the rich.⁵

It is essential to recognize that Wright does not hold that there is any problem of inadequate incentives to provide the amount of investment now taking place (or now attempted). Indeed, if there were, *inflation would not be our secular outlook*. "Only if we deliberately attempt to discourage investment incentives would the case be different. Up to now our discouragement of new investment has not affected the rate of planned investment quite that much."⁶ Wright's argument for tax reduction on high incomes may therefore rather be of a different character, a character which is there largely by implication, not through clear statement. Perhaps it can be stated as follows. Today we have a sum of attempted investment plus attempted consumption that is too great. It is not enough merely to reduce consumption to the extent necessary to avoid inflation. We must rather reduce consumption still more than this, and provide for a still higher rate of investment than now attempted. To do this we must not only *increase the tax burden*, which will reduce consumption, but we must *redistribute it in favor of the rich*, which will increase investment. An actual reduction of taxes on the rich is indeed necessary to *this* argument.

⁴ "Income Redistribution Reconsidered," in *Income, Employment and Public Policy, Essays in Honor of Alvin H. Hansen* (Norton, 1948), pp. 159-76.

⁵ To be sure, Wright's suggestion that the tax reduction take the form of an exemption on saved income would tend to reduce the consumption of the rich, but only if the rate on income not saved were raised sufficiently high. If the rate were not sufficiently increased on income not saved, the rich might end up merely with lower taxes, higher saving, and higher consumption, and the inflationary pressures be increased. The suggestion is worthy of study, but, it seems to me, only if we are willing to concede in advance that it may be worthwhile to bribe the rich to decrease consumption by allowing them to pile up, more rapidly, claims to future income. This, again, is a question of values. Reducing consumption by higher taxes does not have this by-product.

⁶ "Inflation and Inequality," p. 895. The sentences quoted follow this curious one: "Supposing that we do all we can to discourage consumption, the probabilities are that the secular need for current new investment would still be greater than the saving flow." If doing "all we can" includes added taxation, what does this mean?

I may be mistaken, of course, that this is what Wright has in mind. At one point he speaks of lowering taxes on the upper incomes "in order to get more saving *and more investment*" (italics mine). At other points he might be understood to be arguing merely that we need to avoid inflation without reducing investment from its present attempted rate. But in view of his previously quoted position regarding the strength of present investment incentives, it would not seem that reduced taxes on profits and on the rich would be necessary if the objective were merely to avoid reducing investment from its present attempted rate. It is this which leads me to the interpretation I have suggested above: tax redistribution is advocated as a means of securing increased investment. If investment incentives are now strong enough that we are threatened with secular inflation, why otherwise would we need to increase them?

Now this case for a combination of both higher and less progressive taxes must rest on two propositions, neither of which Wright assays systematically, if at all: (1) There is a "welfare" case for a greater rate of investment than now attempted; and (2) Tax reductions on profits and on high incomes will induce a rate of investment greater than that now attempted, and this is the only or the best method of securing added investment.

Take the second proposition first. Accept for argument's sake Wright's view that we want *private* rather than public investment. Is it clear that greater bait for potential investors is the only or the best method to get added investment? One whose value judgments as to the desirability of inequality on ethical and political grounds differ from Wright's might insist that we first try tax reforms of other sorts, monopoly busting, patent reforms, subsidization of technical research, elimination of uncertainties regarding future government actions, and similar measures. In any case, he would put the emphasis on profits taxation rather than income taxation.

But whether Professor Wright is arguing for a rate of investment greater than that now attempted, or merely maintenance of the present rate; whether or not he convinces us that reduced taxation of profits and high incomes is the only or the best way to stimulate investment; he fails, it seems to me; to face up to the vital question of how to justify this high rate of investment. He assumes, that is, that there is an obvious welfare case for a high rate of investment. Why is this obvious?

Grant it to be true that "all over the world today, and even in our own country, the masses of mankind are striving for and demanding a standard of living which our present equipment is inadequate to furnish," Professor Wright is aware, I am sure, that we are here back on classical battlegrounds. What is the optimum rate of capital accumulation if it is not necessarily merely the rate required to provide full employment without inflation? Was not the classical answer (assuming full employment) that it was the rate at which marginal time preference equals marginal product of additional roundaboutness? Would not the Classical answer to the present situation be that the rate of interest should rise, increasing saving and curbing investment? This seems to be part of Professor Wright's answer too. But to the extent that equilibrium is restored in this way it involves a *reduction*

of investment as well as a possible (probably slight) decrease in consumption (increase in saving). Nowadays we attach little enough importance to the effect of the interest rate on investment, but we all assume (I believe), that its effect on saving is even less. Hence, rising interest rates would eliminate inflation primarily by curbing investment, exactly the opposite effect from that which Wright seeks. Certainly, if we desire not to reduce investment, it would be better to eliminate inflation by curbing consumption through added taxes. This points up, of course, the deficiency of the "natural rate" criterion for capital accumulation: what is the natural rate depends on the income distribution and tax structure.

Or does Wright have some other welfare criterion for determining the appropriate rate of capital accumulation? Do the masses acting through government know better than the masses acting as spenders of their own incomes what rate of capital accumulation they prefer? Or does a wise governmental elite know better than the masses acting either way what we and our unborn children want and deserve?

Perhaps welfare would be increased if we saved-invested more, but neither the welfare economists (Lerner in *Economics of Control* argues that this must be a "political" decision) nor Mr. Wright have told us on what grounds we should make this decision. We are all in favor of higher standards of living. But it is not that simple. The question is how far shall we reduce the standard of living in order to increase it. This is a profound and vital question, worthy of careful analysis. If our secular outlook were stagnation, perhaps there is no question: except for times like these, when investment should be discouraged, it is in the social interest to increase investment incentives to the maximum extent possible, and consistent with our distributive ideals (although this may merely intensify the problem subsequently). But if our secular outlook is inflation, we can not ignore the choice that confronts us, and economists need do more than to recognize that it is a choice. For those who believe secular inflation to be our outlook, here is a challenge for careful, original analysis.

Finally, as to whether or not secular inflation is our prospect, I feel incompetent to judge. I only quote a warning from Professor Wright: "Whenever prosperity appears, even momentarily, there are always people to exclaim that 'happy days are here again.' We are in a 'new era.' There will be no more depressions. . . ."

"Shall we be like army officers always preparing to win the last war? During a boom, will our graduate students be trained primarily to prevent inflation—and hence be unprepared in slump? Will they in slump be trained primarily to prevent slumps and so let the next boom become an inflation?"⁷ Unlike the businessman, whose estimate of the future is, we say, excessively colored by today's events, must not the economist always be sure to wear lenses corrected for myopia?

GARDNER ACKLEY*

⁷ D. M. Wright, "The Future of Keynesian Economics," *Am. Econ. Rev.*, Vol. XXXV, No. 3 (June, 1945), pp. 306, 307.

* The author is associate professor of economics at the University of Michigan.

Inflation and Equality: Rejoinder

Professor Ackley impliedly concedes the basic factual assumption of my paper: the marginal propensity to save of the well-to-do is greater than that of the lower-income groups. He also (end of his sixth paragraph) spells out correctly my fundamental contention and concedes its logical validity. I did mean that the flow of net private investment ought to be (secularly) higher, and I do feel that the present aggregate net private (secular) inducement to invest, still more particularly that for risk-taking new ventures, under our present tax-wage-price control outlook, is only adequate where the (proportional) secular level of consumption is very high—too high.

Blaming the inflation on "excessive investment" alone seems to me true, even formally, only as tautology. The real stimulus can come from the consumption side. We might put the matter as follows: the people have become accustomed to demanding a certain *rate of increase* of real income. Price control and restriction of investment might, for a time, halt inflationary price rise. But *real* income might not be *rising* sufficiently. Therefore, there might be demands for "fourth-round" money wages increases, etc., which could start the inflation going again. Sometimes eliminating all saving-investment might not suffice to meet the demand for present consumption.

Since Dr. Ackley concedes my basic point, the real question becomes, as he says, one of values.¹ For brevity's sake I must discuss his main point only. Do not Dr. Ackley's doubts as to whether there is a "welfare case" for a higher rate of investment imply a sort of "iron law of consumer satisfaction"? Of course he does not commit himself to such a position, but would not the logic lead to some such statement as "all income levels are about equally satisfying (or unsatisfying). Progress is a delusion."

Now, if the public agreed, there would be no more to be said. But I believe in (1) democracy and (2) our duty as economists to help the people toward an *informed* choice. I say to the lower-income groups, "You want a rapidly rising standard of living. To get it more capital is needed, to get more capital we need more investment. Some moderation in your demands for equality today will give you more goods tomorrow—without inflation."²

It is important to realize that Dr. Ackley does *not* dispute the correctness of this argument under the circumstances assumed. What seems tentatively suggested is some such reply as this: "No, no, people of America, you will be just as unhappy no matter what your national income is. Equal distribution will give us 'enough' goods. Forget about growth."

I see nothing mysterious about the way to settle this argument—democratically. Leave it to the people through their representatives to make the

¹ For detailed statement of my values see *Democracy and Progress* (New York, 1948), especially the chapter on redistribution. Dr. Ackley is not correct in saying I argue for "inequality." I argue for as much *equality* of opportunity as we can get. Perhaps it might be best to say I argue for a *balance* of equalities, none of which can be wholly realized.

² Regarding the cycle, I have also shown, in *Economics of Disturbance* (New York, 1947), that there is a more or less insoluble conflict between demands for *prompt* satisfaction and demands for perfect stability.

choice: More equality today *versus* more butter tomorrow. But it should be an *informed* choice, a choice by an electorate that understands the alternatives, and is not misled by rosy delusions that we can get "plenty," now, merely by redistribution.

Only one technical point needs mentioning. Dr. Ackley seems to feel that under *any* circumstances raising the market rate of interest will "reduce investment." This is a widespread misconception of Keynesian theory. Inflationary "forced saving" is, of course, one way—possibly the characteristically socialist way (*vide* Russia)—of getting capital formation. But I assume we are agreed that this method is bad. Accordingly, we desire only investment without inflation. Now *ex ante* investment in excess of *ex ante* saving will tend to produce inflation. Raising the rate to an equilibrium figure, under such circumstances, will not reduce the amount of realized *noninflationary* investment. It will only cut off the margin of attempted investment "causing" the inflation! If we want *more* investment, without more inflation, then we want to increase the rate of *ex ante* saving—which is the point I started off with. The appropriate interest rate then would be the one rationing the increased flow without inflation.

In conclusion, I would like to remind my readers that my communication referred to the *secular* problem. Dr. Ackley quotes my "Future of Keynesian Economics."³ I stand by that article in full. If serious depression begins, deficit finance and public works should, in my opinion, be integral *parts* of an effective program. This, however, does not affect secular policy. If private saving-investment would be needed again soon (and they will be if we adopt intelligent policy), we would be very foolish to liquidate the inducement to save for the sake of a short-run crisis.

DAVID McCORD WRIGHT

University of Virginia

Income Elasticity of Demand for Imports and Terms of Trade

The results which Pigou arrived at in solving the problem of transfer in terms of marginal utility functions¹ were elaborated and implemented in the form of diagrammatic analysis by Professors G. A. Elliott and J. Viner.² Viner further improved Pigou's methods by another procedure which does not resort to utility analysis but is still based upon the assumption that the proportion in which the expenditures are distributed between native and imported commodities remains unaltered in the two countries in the absence of relative price changes, as the amount available for expenditures varies.

¹ A. C. Pigou, "The Effect of Reparations on the Ratio of International Interchange," *Economic Journal*, Vol. XLII (1932), pp. 532-43.

² G. A. Elliott, "Transfer of Means-of-Payment and the Terms of International Trade," *Canadian Jour. Econ. and Pol. Science*, Vol. II (Nov., 1936), pp. 481-92. J. Viner, *Studies in the Theory of International Trade* (New York, 1937), pp. 336-60.

Professor Viner's conclusion is limited to a special case and can be shown by means of indifference curves⁸ in the analysis of transfer problem.

In order to make our analysis throughout this discussion manageable, it is demonstrated in terms of a two-country-two-commodity case. In Figure 1, each country has a family of homogeneous indifference curves.⁴ The ordinates and abscissas of both countries A and B are expressed in physical units which are so chosen that A's and B's commodities are equal in price, with ordinates representing imports and abscissas, domestic goods.⁵ The line ab

FIGURE 1

denotes all possible combinations of domestic and imported goods which country B can purchase with a given national income at the prevailing price before capital export. Country B will seek the preferable combination, *i.e.*, the combination on the highest possible indifference curve, which is I_1 , and will buy od of domestic goods and ok of imports.

The a'b' in Country A, which is analogous to ab in B before capital movement takes place, touches the highest indifference curve I'_1 at c'. As a result, od' domestic goods and ok imports will be purchased by A. Draw such a

³ T. Scitovszky, "A Reconsideration of the Theory of Tariffs," *Rev. Econ. Studies* (Summer, 1942) pp. 93-95, for community indifference curve.

*The assumption of a family of homogeneous indifference curves is another way of expressing the linearity and similarity of the utility function within each country, or Viner's assumption that "in the absence of relative price changes, changes in the amounts available for expenditure on the respective countries resulting from reparations payments will not affect in either country the proportions in which these expenditures are apportioned between native and foreign commodities."

⁵ With the assumption that the physical units are so chosen that A's and B's commodities are equal in price, all the price lines must be 45° (Fig. 1). For instance, oa' must be equal to ob' .

line $g'h'$ parallel to, but to the left of, $a'b'$ so as the difference between oh' and ob' ($h'b'$); og' and oa' ($g'a'$) would represent the amount of capital received by A; and of' and om represent the amount of A and B commodities respectively which A would consume after receiving capital, since e' is the point on the highest indifference curve which $g'h'$ can meet.

In country B, draw a line parallel to, but to the left of the line, ab , with the difference between ob and oh (bh); oa and og (ag), representing the amount of capital export, and of and on , representing the amount of B and of A commodities respectively which B would buy after capital export.

Now we are in a position to reproduce Viner's argument by means of our apparatus. He assumed that before capital movement each country spends more money on her own than on the other country's commodities, and, in the absence of relative price changes, the terms of trade will turn against the exporter of capital.

By assumption, $f'o : om = d'o : ok$ because I'_2 and I'_1 belong to a family of homogeneous indifference curves, and $g'h'$ is parallel to $a'b'$.

$$\therefore f'd' : km = d'o : ok$$

By assumption, $od' > ok$

$$\therefore f'd' > km, \text{ and similarly, } fd > kn$$

Since capital movement results in an increase in A's spendable funds equalling the decrease in B's spendable funds,

$$\begin{aligned} f'd' + km &= fd + kn \\ \therefore f'd' &> kn \text{ and } fd > km \end{aligned}$$

It is evident that Viner's result is obtained through assumption, among other things, of a fixed ratio in which countries A and B would divide their respective expenditures between A's and B's commodities, *i.e.*, $od' : ok = of' : om$; $od : ok = of : on$, or, in other words, that $oc'e'$ and oec should be straight lines. But the proportion of expenditure between native and imported goods, in the absence of price changes, remains unchanged by variations in the aggregate amount of spendable funds only when income elasticity of demand for imports is equal to unity.⁶ It is, therefore, a special

⁶The demand for imports can be represented algebraically by a functional relationship between the national income (Y) and the amount of expenditure on imports, M . Thus:

$$M = E(Y) \dots\dots\dots (1)$$

$$\text{The elasticity of demand is given by the formula } E = \frac{dm}{dy} \div \frac{m}{y} \dots\dots\dots (2)$$

As the derivative $\frac{dm}{dy}$ is almost invariably positive (since a rise in national income always brings about an increase in the expenditure on imports), E , therefore, is also positive. Solving the differential equation (2)

$$M = KY^E \dots\dots\dots (3)$$

This is the equation of a demand for imports of constant elasticity E . If the demand curve has unit elasticity, this equation becomes

$$M = KY \dots\dots\dots (4)$$

The curve then becomes a straight line passing through the origin.

case, because there are other cases in which an elasticity could be greater or smaller than unity.⁷

There are three probable cases of elasticity of demand between the two extreme cases of a perfectly elastic demand and a perfectly inelastic demand, namely, (1) A relatively elastic demand (M_3), (algebraically, between $+1$ and $+\alpha$); (2) Unit elasticity of demand (M_1), (the algebraic value is $+1$); and (3) A relatively inelastic demand (M_2), (the algebraic value is between 0 and -1). Similarly, there can be five types of income elasticity of demand for imports in the other country. The terms of trade, after the capital movements have taken place, will also, *inter alia*, be conditioned by the possible combinations of income elasticities of demand for imports of the two countries.

We shall concentrate our attention on the three more probable cases of income elasticity and analyze their effects on the terms of trade. Let M_1 and M_1' be the curves of type (2) in countries B and A respectively, M_2 and M_2' for (3) and M_3 and M_3' for (1).

The combinations of the types of income elasticities in countries A and B are tabulated as follows:

Terms of Trade for Country B—Exporter of Capital

$M_1 M_1' - M_2 M_1' - M_3 M_1' ?$

$M_1 M_2' - M_2 M_2' - M_3 M_2' ?$

$M_1 M_3' ? M_2 M_3' ? M_3 M_3' ?$

Therefore, even when the situation was considered before price changes had occurred, cases could be developed in which adjustment to the transfer might involve changes in the terms of trade in favor of the paying country, against the paying country, or no change at all.

Our scheme can also show diagrammatically how parallel monetary expansions could take place with the balance of payments being undisturbed. Let us put the question in this way. If there is an expansion of income from gh to ab in Figure 2, with an increase of mn imports to country B, how much income expansion should occur in A so that there is an equivalent amount of imports from B? The process of geometric construction will be as follows:

Let us suppose that the distribution of expenditure between domestic and imported goods of countries B and A at all levels of income is represented by P and P_1 respectively. (1) Draw a horizontal line parallel to X-axis

⁷Mr. M. Bronfenbrenner, in an elaboration of Pigou's analysis, has shown that the terms of trade of the capital export country depend, besides price elasticities, upon income elasticities and upon what he called intercommodity elasticities, and has given a general mathematical solution to the problem. The indifference diagram which measures two commodities along its two axes is useful and instructive in showing that Viner's diagrammatic scheme based on Pigou's mathematical condition is under the assumption of, among others, unitary income elasticities of imports. It may be observed that in any scheme of analysis in which the consumers can only divide their incomes between purchases of two goods and cannot possibly buy other goods than these two, there cannot be anything but a substitution relation between the two goods. The problem of analyzing the effects of international transfer would be more complicated if there are more than two goods on which consumers can spend their incomes, because in that case both complementary and substitution relationships would be possible. See M. Bronfenbrenner, "International Transfer and the Terms of Trade," *Studies in Mathematical Economics and Econometrics*, edited

the basis of those assumptions alone, however, Kindleberger's conclusion was clearly a *non sequitur*. Additional assumptions were necessary to ensure its formal validity.

In his communication Kindleberger now comes forth with two such assumptions, namely, the existence in foreign countries of (a) a high rate of induced investment (presumably on a scale more than offsetting the increase in saving associated with the rise in foreign incomes), or (b) a negative marginal propensity to save. I venture to suggest that had he explicitly introduced either of those assumptions in his original article he would have been spared most of the gibes from his Washington friends to which he refers, although I rather suspect that he might still have received a residual of gibes for having attempted to construct a general theory of chronic dollar shortage on such a basis. Unless some such additional assumptions are postulated, the theoretical presumption must be that an increase in a country's exports, far from leading to a greater increase in its imports, will typically result in only a smaller, or at best an equal, increase. By now admitting the need for specifying further conditions, Kindleberger is in effect conceding at least one of the points that his critics had in mind. I had raised that point myself in an unpublished memorandum in 1944 which had been used by Professors Enke and Salera as the basis for the discussion of dollar shortage in their *International Economics*. But Enke and Salera did not point out, as I had explicitly done in my memorandum, that Kindleberger's contention regarding overcomplete adjustment to increases in American imports could indeed be theoretically valid if additional (but what I regarded as special) assumptions regarding induced investment (and other factors) were postulated; and they implied, obviously incorrectly, that an overcomplete adjustment was inconceivable. I had not, it is true, explicitly referred to a negative marginal propensity to save as another condition that would make Kindleberger's argument formally correct, but I did not, and most certainly do not, as he suggests, deny the possibility of such.

The real issue involved is not whether Kindleberger's particular point is theoretically valid, for if fortified by the appropriate assumptions it would be, but whether or not those assumptions are the most realistic ones to make. Apparently Kindleberger believes that they are, and he argues that in his original article he was interested, not in "economic models," but in "the behavior of real economies" (*op. cit.*, p. 492). It is my opinion, however, that he is dealing with special cases, not with the general one, and that consequently he is greatly exaggerating the importance in the real world of the sequence he outlines.

To express the issue in simple yet formal terms: is the marginal propensity to invest in foreign countries as a whole characteristically greater (in alge-

are, of course, quite distinct, as I noted in an article in the *Canadian Jour. Econ. and Pol. Sci.*, Vol. VI (1940), pp. 519-20 n. A continued loose usage of concepts is evident in Kindleberger's note when he speaks of a country with "a high foreign-trade multiplier and a *high* propensity to import" and of a country with "a low foreign-trade multiplier and a *low* propensity to import" (italics mine), *op. cit.*, p. 492. For surely a high foreign-trade multiplier is associated with a low marginal propensity to import, and conversely.

braic terms) than the marginal propensity to save? If so, then increases in American imports would, as Kindleberger argues, tend to cause greater increases in American exports, *i.e.*, to bring about an overcomplete balance-of-payments adjustment. If the opposite situation prevails, increases in our imports would tend to cause only an incomplete adjustment. If the propensities were exactly equal, increases in our exports would tend to be identical to the original increases in our imports.⁴

It may be admitted that in certain underdeveloped countries where the marginal propensity to save is very low (and indeed under certain conditions negative⁵), where there is a high rate of induced investment,⁶ and where the marginal propensity to import *American* goods is high, an increase in American imports from such countries might well lead to an even greater increase in their imports from the United States. But it would, I believe, be unrealistic to assume—and I have as yet seen no statistical evidence to suggest—that the

⁴ This formula merely rephrases one laid down in a broader context by L. A. Metzler, "The Transfer Problem Reconsidered," *Jour. Pol. Econ.*, Vol. L (1942), pp. 408 ff. See also J. J. Polak, "The Foreign Trade Multiplier," *Am. Econ. Rev.*, Vol. XXXVII, No. 5 (Dec., 1947), especially pp. 896-97, and F. Machlup, *International Trade and the National Income Multiplier* (Philadelphia, 1943), p. 184 n. Kindleberger's assumptions regarding the relative magnitudes of the relevant propensities in foreign countries would seem to correspond to the case of economies designated by Metzler as "unstable in isolation." It may be of interest to note that Metzler believes that few countries are in the "unstable" class and that, consequently, income movements induced by international shifts in purchasing power will be inadequate to bring about full balance-of-payments adjustment to disturbances.

Professor W. F. Stolper, using a more sophisticated set of assumptions, has recently argued that Kindleberger's point could be valid even if foreign countries were not "unstable" at all. See his article, "The Volume of Foreign Trade and the Level of Income," *Quart. Jour. Econ.*, Vol. LXI, No. 2 (Feb., 1947), pp. 305-08. But Stolper's assumptions seem to me of an even more special sort than those now introduced by Kindleberger. See also the critique of Stolper's over-all argument by G. Haberler, "The Foreign Trade Multiplier: Comment," *Am. Econ. Rev.*, Vol. XXXVII, No. 5 (Dec., 1947), pp. 904-06.

I can think of several other sets of special assumptions that would make Kindleberger's thesis formally valid, but these need not be elaborated here.

⁵ Since Kindleberger chooses to introduce the possibility of dissaving as a factor tending to cause overcomplete international adjustment (although he admits that "in general, individuals tend to save more as incomes increase"), he should not overlook the possibility of induced *disinvestment* as a factor working in the opposite direction. A rise in a country's exports might at times be associated for a considerable period with substantial net drafts on existing stocks of exportable and other goods. Such induced disinvestment, even in the face of dissaving, would tend to make for an incomplete adjustment, unless the dissaving were larger than the disinvestment in absolute terms, *i.e.*, unless the marginal propensity to invest were greater in algebraic terms than the marginal propensity to save. For an interesting illustration of such induced disinvestment in actual practice, see A. F. W. Plumptre, "The Distribution of Outlay and the 'Multiplier' in the British Dominions," *Canadian Jour Econ. and Pol. Sci.*, Vol. V (1939), pp. 369-70.

⁶ I am using the term "induced investment" here in a broad sense to include all increases in domestic investment associated directly or indirectly with rising exports, namely: increased investment in export and domestic-goods industries induced (a) by rising national income (*i.e.*, the acceleration effect); and (b) by increased availability of loanable funds and/or lowered interest rates that might be brought about by an increase in external monetary reserves resulting from the rise in exports.

marginal propensity to invest in foreign countries as a whole is characteristically in excess of the marginal propensity to save so as to create an underlying tendency for increases in aggregate American imports to bring about greater increases in our aggregate exports. Although I am somewhat skeptical of attempts to prove or disprove Kindleberger's point by reference to the actual statistics of American imports and exports, given the large number of autonomous factors at work affecting each, it seems to me significant that during the interwar period increases in our imports were characteristically associated with smaller, and not with larger, increases in our exports.⁷

Kindleberger attempts to support his thesis statistically by reference to the balance-of-payments experiences of Argentina and Australia in 1935-38. But, apart from my skepticism regarding a statistical approach to this problem, particularly from the viewpoint of the balances of payments of individual foreign countries, and the fact that I consider highly inappropriate his selection of countries, I fail to find his evidence even mildly convincing. All that the Argentine statistics indicate is that the rising exports of Argentina in 1935-37 were accompanied by smaller increases in imports (the active trade balance rising steadily in these three years), and that the decline in exports in 1938 was accompanied by a smaller decline in imports (leading in this case to a deficit). Far from supporting Kindleberger's argument, this episode seems to indicate nothing more than the opposite, and normally anticipated, pattern of developments.⁸ If his point were indeed valid, it would appear that the active balance should have *decreased* year by year and have possibly resulted in a deficit at the top of the boom in 1937. Even if the deficit that emerged in 1938 could be construed as evidence of a belated overcomplete adjustment, the statistics cited by Kindleberger refer only to Argentina's *global* balance-of-payments position, and not the position *vis-à-vis* the United States. For similar reasons, I do not find the Australian experience any more convincing, even though total Australian imports did continue to rise in 1938 (though at a sharply reduced rate) when exports declined.

In my original memorandum I had stated that if, as Kindleberger argued, increases in American imports tend to provoke greater increases in exports, the opposite result would seem to follow when imports decline, *i.e.*, a decline in American imports should provoke a greater decrease in exports and thereby

⁷ For a suggested explanation of that pattern, see my paper, "The Mechanism of Adjustment of the American Balance of Payments: 1919-29," *Quart. Jour. Econ.*, Vol. LVII (1942-43), pp. 363 ff.

⁸ Indeed, Kindleberger himself haltingly admits that his statistics might merely reflect "the effects of alternate rising prosperity and depression in the United States" (*op. cit.*, p. 493.) His attempt to show, *via* the composition of Argentina's imports, that the 1935-37 boom in that country was accompanied by *some* induced investment is quite irrelevant for his argument. The really relevant consideration would have been whether or not that investment was *large* enough (relative to saving) to bring about an overcomplete adjustment.

In any case, Argentina's foreign trade in these years was subject to so many highly abnormal influences that I would consider the episode almost worthless for purposes of testing the validity of this argument. See, *e.g.*, V. Salera, *Exchange Control and the Argentina Market* (New York, 1941), Chaps. 6 and 7.

tend to bring about a dollar "surplus." To be sure, I was aware that the relationship need not necessarily be symmetrical for upswings and downswings, but it seemed to me that the burden of the proof as to why this was not so rested with Kindleberger. In his communication he now argues for the irreversibility of his argument on the ground that "it is possible to regard the demand for commodities in international trade as elastic with respect to increases in income and inelastic with respect to decreases," and he refers to the fact that "luxuries have a habit of becoming necessities" (*op. cit.*, p. 494). What I presume Kindleberger means is that whereas the marginal propensity to invest in foreign countries is characteristically in excess of the marginal propensity to save in periods of rising income, so that there is a tendency towards overcomplete adjustment to increases in foreign exports to the United States, the reverse is true in periods of declining income, so that there is only an incomplete adjustment to decreases in such exports.⁹ But, in any case, evidence for this alleged asymmetry is not forthcoming.

Even if one granted the *general* validity of Kindleberger's contention that increases in American imports typically tend to provoke greater increases in exports—which I do not—it would be an entirely different matter to conclude, as he does, that this sequence provides a theoretical explanation for the alleged tendency toward a chronic world shortage of dollars. I would argue that before such a conclusion could be reached additional—and again, I submit, special—assumptions would be necessary. But this involves a far more fundamental problem that lies outside the scope of this note.¹⁰ May I suggest only that before talking of *chronic* dollar shortages one might do well to examine much more closely the concept of "dollar shortage" itself. In this connection Kindleberger might want to reconsider his own bald definition of a dollar shortage as the existence of a surplus in the American balance of payments on current account.¹¹

I hope that the foregoing remarks do not constitute an abuse of Professor Kindleberger's amiable offer "to negotiate on a generous basis" with any critic who contends that he exaggerated the importance of his argument.

ARTHUR I. BLOOMFIELD*

⁹ See also *op. cit.*, p. 493, n. 12. I might be inclined to agree that adjustments to increases in exports tend to be *more complete* than adjustments to decreases in exports. But this is not the point that Kindleberger is presumably attempting to prove (or, rather, should prove).

¹⁰ For some recent suggestive contributions to this problem, see the articles by G. Haberler, T. Balogh and P. A. Samuelson in *Foreign Economic Policy for the United States*, ed. by S. E. Harris (New York, 1948), pp. 426-45, 446-89, and 406 ff.; H. S. Ellis, "The Dollar Shortage in Theory and Fact," *Canadian Jour. Econ. and Pol. Sci.*, Vol. XIV, No. 3 (Aug., 1948), pp. 358-72; F. D. Graham, "The Cause and Cure of 'Dollar Shortage,'" *Princeton Essays in International Finance*, No. 10 (Jan., 1949); J. Tinbergen, "Observations sur le Problème de la Rareté du Dollar," *Rev. d'Econ. Pol.*, Vol. LVIII, No. 1 (Jan.-Feb., 1948), 36-56; and S. E. Harris, "Dollar Scarcity," *Econ. Jour.*, Vol. LVII (June, 1947), pp. 165-78.

Rejoinder

I am disposed to accept Dr. Bloomfield's plea of *non mea culpa* in the matter of the Bloomfield-Enke-Salera contention that it is impossible for a country to overcompensate in response to an increase in its exports and end up with an import surplus. I trust he will make a satisfactory settlement with Messrs. Enke and Salera whom he has tossed to the wolves. I would, moreover, ask for dismissal of his countercharges of unfairly eliding assumptions and inelegance on the grounds of irrelevancy.

Two possible issues remain—one of logic, the other of experience. Dr. Bloomfield's contention that logic runs in favor of a presumption that all propositions are symmetrical cannot be accepted. I know of no authority for this bizarre bit of reasoning. Asymmetry at one level, moreover, may be symmetry at another level. If in the short run a country may spend more than its increase in earnings, there is no reason that it should save more when its earnings decrease, although this result is possible. It may be, moreover, that an explanation of the dollar shortage of some considerable generality may be found—if not alone in the tendency of certain other countries to overcompensate with respect to increases in exports—in this, in a tendency to undercompensate with respect to decreases and in opposite tendencies in the United States to undercompensate in respect to increases in exports and overcompensate with respect to decreases. In this explanation there is no symmetry within or between countries; but the over-all model is as symmetrical as anyone might wish.

I am not disposed to debate the facts with Dr. Bloomfield. I have acknowledged the difficulty of verification, although I do not go all the way with Dr. Bloomfield, who appears to despair of empirical testing of any proposition in this field. I cannot, however, accept the proposition that, because more theoretical models have been built by scholars with a tendency to undercompensate than with the opposite tendency, there is a strong argument in favor of the prevalence of this tendency. Without claiming that this makes Dr. Bloomfield "it" in the game of "burden-of-proof" tag, I suggest he might look into the Latin American experience of 1946-48 to see how large dollar deficits can be developed under the stimulus of expanding export sales to the United States; or into the nineteenth-century experience of Britain's debtors who borrowed more in prosperity when their exports rose; or into the history of corporations which have grown prosperous by going into debt.

C. P. KINDLEBERGER*

Libertarianism at Bay

Said Frank D. Graham to Barbara Ward:

"Your economics are deplored.

Your deficit to evaporate

You merely need depreciate."

Said Barbara Ward to F. D. G.:

"The trouble seems more deep to me.

I don't believe the fix we're in

Comes purely from original sin."

In writing this note, the author has no intention of restating why he believes Barbara Ward's *The West at Bay* to be on balance a good book, in the face of Mr. Frank D. Graham's conviction that it is "a subtly dangerous and a highly subversive one."¹ The author is sympathetically predisposed toward Mr. Graham's liberal premises and is in agreement with many of his specific criticisms. But he is in radical disagreement with Mr. Graham's perspective and therefore with his conclusions. The purpose of this note, then, is to question the manner of Mr. Graham's review and to express a doubt whether, despite the self-assurance of his attack, he may have missed the main points of Miss Ward's essay.

There has emerged in recent years a new fashion of egregious rudeness among self-styled "libertarians," who castigate the heretics with such vigor as to cast doubt on the libertarians' confidence in the weight of their logic. In Great Britain, this fashion has been so perfected in the postwar years that it threatens to replace constructive economic criticism by mere dialectical sniping. From the observer's point of view it is often fun to watch the pyrotechnics. But it hardly befits the aspirations of a fledgling social science to treat other earnest searchers for truth in the manner of Lysenko's disciples driving Mendelians from the temple. Nor can the easy victory of the *argumentum ad blurbum* be expected to carry much weight with an audience more interested in the content of a book than with the encomium on its jacket.

It might be argued that the libertarian onslaught is not intended to advance economic understanding or the state of the science among professionals, but is rather directed toward the makers of public policy, or even more broadly toward public opinion in general. If this is the case, the Hayek-Mises-Jewkes-Graham manner (the list does not pretend to be exhaustive) hardly seems well designed to its purpose. Anyone with the merest nodding acquaintance with the professional literature knows that the supposedly self-evident truths and indisputable verities of the libertarians are hotly disputed among the "experts." The layman also observes that in the real world such problems as inflation control, the maintenance of high employment, the provision of reasonable economic stability for agriculture, and the achievement of equilibrium in international trade without intolerable reductions in

¹ See this *Review*, Vol. XXXIX, No. 2 (March, 1949), pp. 548-53. It should be noted, incidentally, that neither Mr. Graham nor I had seen the other's review prior to publication.

living standards or politically impossible readjustments in internal economic relationships in various countries, do not in fact give way to easy panaceas. In consequence, while the layman's first reaction to the libertarian prescription may be enthusiastic—since a dose of freedom would satisfy one of his deepest yearnings—he is likely on more sober reflection to wonder if the excess of heat in the libertarian writing does not conceal an absence of light.

The most remarkable single statement in Mr. Graham's review is his assertion that "the 'dollar crisis' . . . is now (and, perhaps, always was) solely a matter of discrepancy between the controlled external (exchange) value of the pound sterling, and other European currencies, and their (lower) internal values" (p. 552). It is really breath-taking to see Europe's postwar economic problems disposed of so neatly and casually. There is no hint of the difficulties imposed by the loss of prewar overseas investments, by the wartime destruction of plant and equipment and merchant shipping, by the years of capital depletion, by the disappearance of Germany from the European economy, by the drawing of the economic iron curtain across the heart of Europe, by the changed position of the former colonial areas, by the adverse shift in the European terms of trade. There is no concession whatever (unless it be in the little word "perhaps") to the view that in many of the European countries dollar imports have been reduced to minimum tolerable limits by direct controls and that exports have until recently been as great as could be supplied in view of the war-induced dislocations, so that in the short run devaluation would merely have created added internal inflationary pressures and worsened the terms of trade. There is no recognition of the extreme uncertainty regarding import and export elasticities of demand.

The almost unanimous consensus of those with responsibility for international financial policy over the last few years cannot be effectively disposed of by references to "the tradition of Hjalmar Schacht, Thomas Balogh and the bullionists," who may be assumed to have a liking for nationalist controls for their own sakes. The fact is that most of the responsible officials, laymen and economists alike, would have liked nothing better than to whisk away the European economic problem with a few neatly contrived adjustments in exchange rates. The libertarian views are of little moment so long as everyone recognizes that the whole world is out of step except the libertarians. There may be some disadvantage for the profession, however, if laymen are led to believe that the libertarian dogma is shared by all economists, and there is always the more serious, if less probable, danger that a layman in high office might actually follow the libertarian prescription unalloyed.

A few words are in order, finally, on Mr. Graham's patronizing comment that Miss Ward "writes most engagingly, that her heart is in the right place and that, when she does not get beyond her depth, she swims very prettily indeed." Miss Ward's book is not addressed to professional economists and makes no pretense at being an essay in technical economics. It is guilty of a number of economic "howlers." Its prescriptions of policy would be greatly improved by a sounder technical substructure. But the policy issues of European integration are not exclusively or even primarily economic ones. Miss

Ward's argument draws its greatest strength from its historical, political, and moral foundations. Human society has many dimensions. The economic dimension has been better analyzed than most as a matter of intensive rationalization from narrow abstractions. The motivations of peoples and the policies of nations, however, do not lend themselves to such abstractions and there is ample evidence that they are moulded by other factors as much as or more than by the "purely" economic ones. It takes unusual audacity to be certain that, desirable though it be, a full appreciation of the principle of comparative advantage is more relevant to the problem of European integration than an understanding of the moral foundations of western civilization. One can hardly escape the conclusion that Mr. Graham's swimming suffers from a failure to understand which way is down.

MEMORIAL

Frank Albert Fetter
1863-1949

With the death of Frank Albert Fetter the great company of American economists has suffered an irreparable loss. The profession of economics has grown mightily in numbers and influence in the half century of Professor Fetter's fruitful participation, but it is the paradox of human progress that the loss of a single creative mind cannot be balanced by numbers, knowledge, or prosperity. Rather, new creative minds must arise to the new challenges facing society, drawing not so much upon accumulating evidence for strength, but upon the personality and inspiration of those rare souls who in their time were great enough to recognize truth.

The facts of Professor Fetter's richly productive life are readily available. On his eightieth birthday, two of his colleagues prepared a comprehensive note for the record.¹ It seems fitting, therefore, now that he has completed his course, to comment on those elements of personality and character which must ever be reflected in the creative leaders of our profession if it is to serve mankind in attaining peace and well-being.

Professor Fetter was a friend to all who knew him. He early learned the secret that there is no limit to the richness of one's loyalties. A devoted son, husband, and father, his gentleness and understanding made the circle of his family a place of happiness and peace.

With neighbors, colleagues, and students, his sincere interest in each individual, his sensitivity to another's feelings, problems, and aspirations made him a true friend to an ever-widening circle of people, young and old. Slow to criticize but quick to understand, he helped others by wise counsel, seasoned with never-failing humor. With clear perception he aided all who came to him for guidance to see their problems in the perspective of mature judgment and firmly established values.

From the deep insight into human personality gained over the years as a friend and counselor, Professor Fetter attained a penetrating understanding of both the individual and the community. Before the approach of social psychology was under way, he was ever probing the motives and reactions of individuals and of groups of individuals forming complex societies. He was concerned in what actually took place and not in forcing behavior into a pre-determined mold. He tested his conclusions against those arising in the new discipline of psychology but his Hoosier common sense kept him from being swept away by the enthusiasms of younger pioneers.

Professor Fetter possessed that hall mark of greatness—simplicity. He was approachable to young students and great scholars, to the messenger boy and the president—to anyone in need. He had the capacity of reducing clouded and complex issues to manageable form, often with a touch of pungent humor

¹ *American Economic Review*, Vol. XXXIII, No. 1 (Mar., 1943), pp. 230-35.

that lessened tensions and encouraged objectivity. He had no love for complexity for its own sake. Rather, he sought to trim out the confusion of over-worked pedantry and expose the essential thesis to analysis.

Professor Fetter was never over-awed by man-made authority. He rebelled against the classical economics of his student days and sought to get closer to the workings of the human mind. To him the "economic man" of earlier analysts was a barrier to the deeper understanding of the motives and restraints in human behavior. He thought things through for himself. Thoroughly read in the literature of his field and in the great classics of human thought, he did not permit others to do his thinking for him. It was, perhaps, a blessing that he spent eight years in business before he commenced his professional studies. His guiding rule was: doctors differ—work out your own conclusion.

His love of simplicity and his unwillingness to accept time-honored authority led Professor Fetter into the revision of the whole theory of economic distribution. He was not satisfied by separate, mechanistic explanations, but sought an integrated scheme. He believed that this essential scheme, like most great truths, would be simple, unitary, and consistent. In this he had the sense of dedication of the inspired scholar, whether scientist or humanist, who believes in his soul that God's ways are profound, but never arbitrary. The results of his analysis are still subject to debate. He would be the first to accept this outcome. But he opened new highways into the unknown continent of economic theory, and rekindled interest in pushing out the frontiers of knowledge.

As a teacher, Professor Fetter taught not by precept alone, but by the example of his devoted love for truth. He taught *men* rather than *materials*, and stimulated his students to seek wisdom and to challenge error. His students soon learned that the marshalling of past authority was insufficient to establish any point, and that the proof must arise from one's own understanding and reasoned analysis. His teaching was not a passing on of pre-digested truth, but an encouragement, by high example, sustained interest, and warmth of common understanding, of the student's search for knowledge. To his former students Professor Fetter will always stand, above all, as a guide, counselor, and friend rather than as an exponent of catalogued material.

Throughout his life Professor Fetter was ready to fight courageously for truth as he saw it, at the sacrifice of security, comfort, and health. He was ready to take the harder course of the pioneer and to resist the spiritual corrosion of easy conformance. Although tolerant and understanding of differences of taste, he opposed with great intellectual vigor and incisiveness any departure from the highest standards of scholarly integrity and independence.

But neither scholarship nor teaching alone could satisfy Professor Fetter's sustained urge to improve man's estate. In his earlier years he aided many welfare agencies. He worked for international peace, for the improvement of slum housing, for the institutional care of the sick, and for the improved education of young people in public schools and in correctional institutions. As time passed, he centered his interest in the great threat of monopoly as an undermining force in a free society. In this his deep understanding of economic

forces and his dedication to the public welfare joined to make him a powerful and fearless enemy of confusion and selfish interest. He saw more clearly than any other the growing dangers of the concentration of economic power to the freedom of the individual. Long after most men leave the battle to another generation to carry on, his devotion to the cause of the individual—his freedom and dignity—kept him in the fight against error and ignorance in high places. He spent his last energies in that fight. He died a valiant soldier in the cause of truth.

BOOK REVIEWS

Economic Theory; General Economics

Introduction to Economic Science. By GEORGE SOULE. (New York: Viking, 1948. Pp. 154. \$2.50.)

This book represents a valiant attempt to describe macro-economics in elementary fashion. It succeeds on the descriptive side but falls short of the mark in its analytical efforts. The reader learns a great many interesting facts and figures but is given inadequate guidance in utilizing them. In view of the title, it is also necessary to add that this book does not provide an adequate introduction to either the scope or method of modern economics. It does, however, raise or rather provoke some important questions of analysis. For this reason, more space is devoted to this review than the importance of the book itself would warrant.

The opening chapter is directed against the "classical theory." It is now widely agreed that both the Keynesian and classical systems can make their contribution to the understanding of economic problems. Yet Soule devotes his entire first chapter on "Economic Fundamentalism" to a condemnation of the classical school.

Soule points to five fallacies of the fundamentalists: the fallacies of "concealed premises," "missing quantities," "omitted factors," "separate pieces," and the "fallacy about human behavior." In his discussion of concealed premises, Soule makes the customary attack on *ceteris paribus* analysis. However, his proposal, as indicated in the rest of the book, is merely to substitute aggregative analysis, making use of national income and a few major components. This is a desirable emphasis but Soule fails to realize that national income analysis may be just as dependent on *ceteris paribus* assumptions as is the partial equilibrium analysis attacked by Soule. If we restrict ourselves to just a few broad aggregates, we cannot analyze the effects of, say, an increase in governmental expenditures, unless we make numerous *ceteris paribus* assumptions respecting individual propensities to consume, invest, import, etc., and exogenous changes in every component of national income or forces affecting it, except the ones immediately under discussion. These are thorough-going assumptions and the mere fact that they can be stated briefly should not mislead us—as it has apparently misled Soule—into believing that somehow we have magically allowed everything to vary at once while we carry on our analysis. If the alternative he proposed were either the Walrasian general equilibrium system or the modern econometric adaptations of either the Leontief or Tinbergen-Klein variety, it would be worth while taking his criticism seriously. These alternatives do reduce the necessity of *ceteris paribus* assumptions. Soule does not, however, propose these or even indicate that he is aware of them.

For many problems, *ceteris paribus* analysis may be used profitably. The fact that not all assumptions are stated explicitly, a matter which troubles

Soule greatly, must also be examined before wholesale condemnation is made. There are actually thousands of assumptions involved in any analysis. Most of them are never stated because they are taken for granted by reader and writer: assume that there will be no major national calamity; assume that people will not become vegetarians; assume that traders on the stock market wish to make a profit; etc. Any one of these assumptions might suddenly become unrealistic and the analysis will then be alleged to contain "hidden" assumptions. Nowadays we often preface our analyses with some explicit assumption about war but in the halcyon 'twenties there was no need to mention this eventuality. The assumption was implicitly there nevertheless. The deliberate hiding of a relevant and important assumption whose reality is known to be controversial is, of course, to be condemned; the mere failure to undertake the impossible task of listing all the innumerable conditions which are generally taken for granted must often be condoned as a necessity. Soule's superficial condemnation of *ceteris paribus* analysis is unfortunately shared by many professional economists—until they try to analyze an economic problem themselves. The econometricians have a workable substitute to offer but until their methods are more widely known we shall have to proceed as before with *ceteris paribus* assumptions and the technique of successive approximations to reality.

Soule's discussion of the other "fallacies" is subject to similar qualifications on methodological grounds. His emphasis on the significance of the full employment assumption of the fundamentalists is well placed and the limited applicability of their conclusions is clearly indicated. The resulting condemnation of their entire system is, however, unwarranted. Now that we have full employment and its inflationary problems, we are beginning to appreciate the keen insight which many fundamentalists have displayed.

Those students who have not otherwise become familiar with national income estimates might profitably be assigned the chapter on that subject, "Keeping Books for All the People" (Chap. 2). The chapters on "The National Income as History" (Chap. 3) and "The Gains in Production" (Chap. 4) also provide interesting summaries of factual data from studies of the National Bureau of Economic Research. These three chapters are marred, however, by the fact that references are made to both Kuznets and Commerce estimates without an indication of the definitional differences which exist between them. Moreover, the exposition of Stigler's interesting work on capital-productivity and labor-productivity (pp. 56-58) is not very clear.

The most valuable chapter in the book—from a descriptive point of view—is the one on "Budgeting for the Whole Economy" (Chap. 6). This contains an explanation of the nation's economic budget as presented in the Economic Reports of the President. Teacher and student can profitably read this chapter. Economists who have not as yet become acquainted with the useful macro-economic device of the national economic budget will find that this chapter provides a convenient means of doing so. Undergraduate or graduate students at any level might be assigned this chapter instead of, or as an introduction to, the President's Economic Reports.

One could wish that Soule's interpretation of the nation's economic budget were less mechanistic and that the author were less ready to reach major conclusions on policy with little or no analysis. The argument for control of prices, wages, salaries, and rents is presented in a few simple sentences, "Nevertheless, one of the most important gates at which to control the flow of spending was that of consumers. One obvious way to keep this gate from opening wider was to retain price control. For if consumers did not pay more for each unit, their spending could not increase, unless there should be more goods to buy. But suppose their incomes did increase. What would they do with the extra money? *Clearly they would have to save it. And, in that case, it would probably be invested* at home (that is, spent for capital goods) or invested or given abroad, thus increasing the spending of foreigners. *Even aside from black markets which may make price control more or less ineffectual*, incomes as well as consumer spending must be limited if total demand is to be limited. Therefore, it was important not only to have price control, but to limit rises of wages and salaries and to control rents" (p. 80, italics added). Here we have in quick succession statements that (1) increased income will be saved, (2) the savings will probably be invested, (3) black markets may make price control ineffectual. If the author is certain of (1), what will be the cause of (3)? Can we say that (2) will "probably" occur? There is lacking an analysis of inter-relationships and a review of some of the other relevant possibilities, such as purchase of government bonds, repayment of private debt, spill-over to uncontrolled activities, and many others. The significance of fiscal pressure is discussed on the next page, after the conclusion on price, wage, and rent control is reached. In the discussion of fiscal pressure, there is emphasis solely on the dollar magnitudes of expenditures and revenues: "The critical item here is the *difference* between government receipts and expenditures that is, the cash surplus" (p. 81). One would not expect a detailed consideration of the qualitative aspects of taxation and expenditures in a short book of this sort but there should at least be some recognition of the fact that such qualitative aspects are of importance.

The concluding section of this chapter, entitled "What Happened in 1947," illustrates the dangers of making a causal analysis of a past period merely on the basis of limited *ex post* data pertaining to that period. Figures are given for 1946 and 1947 on consumers' disposable income, consumers' expenditures, business surplus income (undistributed profits and reserves), business investment, net foreign investment, government receipts and payments. Confining himself solely to this information, the author finds, "The increase of investment which occurred was financed not out of larger savings by individuals, but out of larger undistributed profits" (p. 83). This conclusion is reached merely by comparing *ex post* savings with *ex post* investment. As far as these limited data go, the firms which undertook the investment (no break-down is given between capital goods and inventories) may have been financed by the banks while the firms which saved may not have made any investment in capital goods or inventories. The fact that saving must match investment, *ex post*, does not tell us how the investments were actually

"financed." The effects of credit expansion on the income categories are implicit in the national economic budget but the amount of credit expansion does not appear explicitly in the budget.

The chapter on "Ups and Downs of Business" (Chap. 5) is confined almost entirely to a summary of the Mitchell-Burns volume. Soule dismisses other work on business cycles with the statement: "As more attention began to be paid to the problem, a host of explanations was offered for the persistent rhythms of business activity. It would require a long book to summarize the many varieties of business cycle theory. But such a book would be more confusing than enlightening, since most of the explanations advanced have been based on guesses, partial observations, emphasis on one or two factors which overlooked the rest. Many of the theories are mutually inconsistent; some of the better ones fit some of the facts, but none fits all of them" (p. 62). After this broadside, one would at least expect a theory which fits *all* the facts. None is forthcoming.

In the matter of forecasting, the author exercises commendable caution: "Any forecaster who bases his predictions on a definite or average length of the cycle, or in any other way assumes that it is periodic in the sense in which movements of astronomical bodies are periodic, should be scientifically suspect" (p. 65). Later he says, "This does not mean that forecasting is a hopeless task. But it is by no means a mechanical one, to be performed by some simple trick, like noting a weather sign. We may hope eventually to achieve perhaps as high a percentage of success as the weather man, and by as complex methods. Good forecasting would involve, first, an inspection of forty or fifty statistical series to make up one's mind where we stood in a given cycle, and then the use of shrewd judgment about other factors" (pp. 66-67). Such humility, always desirable, is especially so in view of the limited coverage of business-cycle analysis evidenced by this chapter.

The least satisfactory chapter in the book is the one entitled, "How Money Appears and Disappears" (Chap. 7). The explanation of reserves and of the function of legal reserves is confused and inadequate. There is no explanation of how credit expansion is accomplished through individual banks to the banking system as a whole. Suspicions of confusion are confirmed by such statements as, "It (the member bank) can then borrow from the Federal Reserve Bank in order to lend more to its own customers. The maximum amount it can borrow is of course limited by the size of its reserve" (p. 92). Since lending to customers will increase deposit liabilities and thus reserve needs, it is hard to tell just what the author has in mind here.

In his three concluding chapters, "Private Enterprise in Fancy and in Fact" (Chap. 8), "Planning for Employment" (Chap. 9) and "The International Income" (Chap. 10), Soule presents additional factual information that is interesting and valuable. Among the subjects covered are: concentration in industry, the managerial control of enterprise, the Employment Act of 1946 and the President's Council of Economic Advisers, the Monetary Fund, the World Bank and the International Trade Organization. The discussion of the Keynesian theoretical system is generally satisfactory, considering the small space devoted to it. The by-passing of the interest rate and the misconception

of "hoarding" in the following statement, however, leads one to suspect some confusion in the author's mind: "'Liquidity preference' means the preference people with savings may sometimes have to keep their money in cash rather than invest it. This, when it comes into play, naturally decreases investment. (Keynes held that society as a whole could not hoard money; if money was not spent or invested, it would, as a whole, disappear. For the cash one person failed to spend would diminish by that much some other income" [pp. 106-7]). Some confusion in the understanding of the effects of exports on the national income is also apparent. Referring to the fact that a positive net foreign investment appears as a negative item in the nation's economic budget, he says, "The item is a minus one in the budget because we supplied this part of our product without getting anything currently in return. *This accords with the fact that an export surplus is a subtraction from the income of the country that sends abroad more than it receives, though on grounds of policy it may sometimes be desirable*" (p. 137, italics added).

There is appended a convenient bibliography of about twenty items consisting mainly of the works summarized in the text.

This book is apparently intended as an "answer" to Hazlitt's *Economics in One Lesson*. Some of the well-known elementary textbooks in economics, for instance those of Boulding, Morgan, Samuelson and Tarshis, do contain a sufficient explanation of macro-economic analysis to provide a basis for an effective "answer." The present book does not. It contains relevant factual material and makes frequent allusions to the appropriate theoretical system, but it does not provide the reader with a way of thinking about (as opposed to a way of describing) national economic problems. As indicated above, several of the chapters are well worth reading. The book as a whole cannot, however, be recommended as an introduction to a college course in economics. Its influence on laymen and politicians should generally be salutary in that it argues convincingly for the value of economic statistics and for a continuance and expansion of the work of the President's Council of Economic Advisers.

HAROLD M. SOMERS

The University of Buffalo

History of Economic Doctrines: An Introduction to Economic Theory. By EDUARD HEIMANN. (New York: Oxford Univ. Press. 1945. Pp. ix, 263.)

Considering the brevity of his book, Professor Heimann gives a remarkable presentation and interpretation of the leading ideas of economic theory from Aristotle to J. M. Keynes. His volume presupposes no previous training in economics and it can be read with profit by beginners who want a "short course" in economic doctrine. The book is also useful at a more advanced level because of numerous provocative insights and because of the self-conscious attempt to apply a distinctive approach to the history of economic thought. The point of view is modern in the sense that earlier theories are interpreted in the light of recent views of saving, investment, interest, money, and economic fluctuations. The style is simple, non-technical, and lucid.

Professor Heimann's book is an essay rather than a treatise. The purpose

of the essay is "to show the inward logic, revealed in retrospect, of the development of modern economic thinking and thereby to place the study of economic theory in its proper setting" (p. v). Economic theory is defined as the discipline which has been associated historically with the problem of the allocation of scarce resources in a free-market economy. The adjective "free" is used in a technical sense to designate an economy in which no central authority exercises control over the hierarchy of needs and the allocation of scarce means. The task which economic theory set for itself about two hundred years ago was "to discover and analyze the hidden law of co-ordination and integration in a free economy" (p. 9).

Although Professor Heimann conceives economic theory narrowly as a purely technical branch of knowledge concerned primarily with the value problem, he provides a comprehensive setting for explaining its historical evolution. Since his approach appears to be the main contribution of the volume, I shall attempt to explain it. This involves difficulties because Professor Heimann himself has not given a clear presentation of his approach, and his failure to do so is the chief shortcoming of his book. His thesis seems to be that the method employed by an economist determines the results of his theory. Three main elements enter into the choice of method: (1) the pervading spirit of the age, or what Heimann calls "the forms of man's understanding of himself," examples of which would be supernaturalism, naturalism, and historicism; (2) the general techniques of analysis, the most important divisions of which stem from the circular flow theory of Quesnay and the price analysis of Adam Smith; and (3) the position of the theorist in relation to the class struggle and group conflicts of his time. In taking this view, Professor Heimann rejects on grounds of inadequacy the approach which interprets the history of economic theory primarily as a gradual improvement and refinement in the tools of economic analysis (Schumpeter), as well as the approach which sees economic theory primarily as the rationalization of class and group interests (Marx, Roll, Myrdal). He acknowledges truth in both these points of view and to a degree incorporates them into what he considers a more comprehensive interpretation of economic doctrines.

In the age in which economic theory in Professor Heimann's sense arose, man understood himself in terms of a philosophy of the natural harmony of the universe, and from this was derived the idea of a "natural" economic order. Thus the eighteenth-century conception of nature as rational and bountiful is said to account for the optimism of Adam Smith. Although allegiance to a natural order continued into the nineteenth century, the newer view interpreted nature as irrational and niggardly, and in terms of this Professor Heimann explains the pessimism of Malthus and Ricardo. The shift in the nineteenth century from natural science to history as a methodological guide in man's understanding of himself enabled the socialists to blame social institutions rather than human nature for the evils of society and opened the vista to revolutionary programs of social reconstruction.

Quesnay and Smith were both products of the same age and both believed in the tendency of the world toward pre-established harmony, but they did

not employ the same techniques of analysis. Quesnay's circular flow theory is modeled after laws governing biological organisms, which are subject to functional disturbances. From this beginning there developed the modern theories of functional disturbance, *i.e.*, of economic fluctuations. The followers of Adam Smith modeled their principles of economics along mechanical lines, which, according to Heimann, made it impossible for them to develop a theory of functional disturbance and economic crisis (p. 92). It may, however, be observed that Malthus' ability to break away from the mechanical price theory of the classicists to a type of circular flow theory suggests that method may be less of an independent variable than Professor Heimann contends.

Although Professor Heimann considers class and group bias in explaining economic theories, the handling of this aspect of his approach is such as to minimize its importance. To take one example, his discussion of Ricardo completely ignores the vital role of the corn law controversy in shaping Ricardo's theory of distribution. Professor Heimann is eager to exonerate Ricardo from the charge of being an apologist for capitalism, and rightly so, although Ricardo's intellectual integrity hardly needs defending. It would have been enlightening, nevertheless, to have noted that Ricardo's advocacy of repeal of the corn laws was a program favored by industrial capitalists and opposed by the land-owning interests. As Wesley Mitchell has pointed out, Ricardo's theory of distribution gave theoretical expression to the practical question whether "the power of the state should be used to maintain the high incomes of the farmers and landlords, or whether the import duties should be reduced to safeguard the interests of manufacturers and merchants" (*Trend of Economics*, pp. 5-6).

A disturbing aspect of Professor Heimann's approach to the history of economic doctrine is the failure to deal systematically with the criteria of validity of economic theories. He states at one point, "There is, then, no way of avoiding the uncomfortable conviction that . . . the propositions of economics are unverifiable and irrefutable" (p. 20). Literally interpreted, this means that economics cannot hope to be a science since confrontation of theory with the facts of experience is the prime requisite of scientific inquiry. One wishes Professor Heimann had given more consideration to the nature of the appeal to facts in testing the validity of economic theory. In a forthcoming posthumous volume on the history of economic theory the late Professor Rogin develops the thesis that the appeal to facts in economics cannot be made directly from formal theory, but must be made indirectly by appealing to facts through practice, that is, through the practical policies associated with a theory.

In part, Professor Heimann avoids the problem of validity by defining economics as a purely technical branch of knowledge, thus removing questions of policy from economics and placing them in the realms of politics, morals, and philosophy. Since economics is essentially formal, it tells us nothing about the relative merits of various institutional practices. Viewed in this manner, there is, for example, no *economic* issue between capitalism and socialism—the issue is not even political according to Professor Heimann,

but moral (p. 176). By shunting nearly all important questions of policy into other fields, economics is reduced to an insignificant role in the affairs of men. Economists who wish to say anything about policy do so not as economists but as moralists.

In spite of shortcomings, Professor Heimann has made a valuable contribution to the literature on the history of economic doctrine.

DUDLEY DILLARD

Columbia University

Einführung in die Wirtschaftstheorie. I. Teil, *Theorie des Wirtschaftskreislaufs.* By ERICH SCHNEIDER. (Tübingen: J. C. Mohr [Paul Siebeck]. 1947. Pp. vi, 82. RM. 3.)

Taking advantage of the fact that the theories of price, money, business cycles, public finance, and business economics have recently been integrated into a unified, comprehensive economic theory, Professor Schneider has undertaken the task of presenting a new *Einführung in die Wirtschaftstheorie* (Introduction to Economic Theory) in three volumes. The first volume, entitled *Theorie des Wirtschaftskreislaufs* (Theory of the Circular Flow in the Economy) is now before us. Volume Two will treat of the Theory of the Economic Plans of Households and Firms; Volume Three, of the Theory of General Equilibrium, Money and Employment.

Professor Schneider emphasizes that we cannot understand economic processes if we stop at the visible, objective manifestations of economic conduct; and that we must go back to the individual economic plans (of households and firms, and sometimes governments) which are behind them. Yet, the theory of the individual plans is postponed for the second volume. In this organization, in devoting the first part of his work to aggregative analysis, Professor Schneider follows the example of recent English and American economic texts.

Making the twofold distinction between production plans and consumption plans, and between plans freely made by individuals and plans made by central authorities, Professor Schneider, in the first chapter, sketches four "pure" types of economic systems, and then proceeds to the analysis of the free-exchange (individualistic) economy. In the second chapter he shows how the financial statements of individual households, firms, banks, and governments can be consolidated in a "national wealth" account for the economy as a whole.

The core of Professor Schneider's analysis is in the next three chapters, dealing with the economic process in a *closed* economy *without* government activity (Chap. III), in an *open* economy *without* government activity (Chap. IV), and in a *closed* economy *with* government activity (Chap. V). These are, in the main, variations of the Keynesian themes that Saving equals Investment (Chap. III), that Saving equals Domestic Investment plus Export Surplus (Chap. IV), and that Saving equals Private Investment plus Budget Deficit (Chap. V). These main themes, however, are developed in an original way and harmonically combined with subsidiary themes.

The "macro-economic equations" are derived from the income accounts

of individual households and firms. Schneider begins with the accounting system of an individual firm and demonstrates the entries that are made in the books of the firm for each of the six "steps": payments, purchases, costs, production, sales, and receipts (p. 32). He takes the reader through the accounting procedures of the firm in order to lead him gradually to the consolidated national income account. This is an excellent procedure because, among other things, it can clarify, in one pedagogic sweep, as it were, a number of different concepts: gross income, gross investment, depreciation, net income, net investment, value added by manufacture, personal incomes, etc. Unfortunately, the formulation by Schneider is not quite satisfactory, because the exposition of accounting techniques is not sufficiently lucid. Without previous training in accounting, students will hardly be able to follow the argument closely enough to comprehend thoroughly all relevant relationships.

Professor Schneider mentions (p. 53) that all his macro-economic equations reflect merely the flow of goods and services, but not the flow of money; they reflect purchases and sales, but not payments and receipts. He also mentions repeatedly (pp. 47, 49, 52, etc.) that the quantities involved are *ex post* and that the equations therefore do not represent statements of causal relationships. But these warnings are probably more than neutralized by formulations which suggest causal or functional relationships. For example, the equation "Total Income of Entrepreneurs is *equal* to Total Investment *minus* the Saving of Non-entrepreneurs *plus* the Consumption of Entrepreneurs" is called an "especially important relationship" (p. 51) and the conclusion is drawn that the income of entrepreneurs will be higher the greater the amount of investment, the greater the consumption of entrepreneurs, and the smaller the savings of non-entrepreneurs. How many students will avoid the impression that any changes in *any* of the terms on the right side of the equation must *cause* the income of entrepreneurs to change accordingly?

Similarly misleading formulations appear in the analysis of fiscal policy. It is stated, for example, that "the total amount of direct taxes paid by entrepreneurs is irrelevant for the total amount of income of entrepreneurs" (p. 73). Two definitions had preceded the analysis: (1) business taxes were included in "direct taxes paid by entrepreneurs" and (2) taxes were included in the "income of entrepreneurs" (pp. 70-71). In other words, this income was meant to be what we usually call "income before taxes." Does it then take any "proof" to "conclude" that the amount of taxes is irrelevant for the amount of income? But if we are to reach this conclusion from a series of equations, is it not almost inevitable that the reader forget the definitions and attach policy implications to the result? On the same page Dr. Schneider deduces from his equations that "an increase in the budget deficit by a given amount will, *ceteris paribus*, automatically result in an increase of the total income of entrepreneurs by the same amount" (p. 73). How many students will remember that statements of this sort are supposedly without causal significance and, hence, should not be directly applied to questions of economic policy?

The best passage in the book, in my opinion, is the exposition of the relationship between micro- and macro-economics. Since the book is not available in English, I believe I am justified in supplying here a free translation of the essential parts of the passage (pp. 54-55).

"In principle the actual course of the economic process is determined by the decisions and conduct of the individual economic units [the individual households and firms]. Any analysis of the economic process, therefore, must go back to the acting economic units. . . . It is possible in our theory to comprehend the course of the economic process as a result of the interaction of the decisions of the millions of small economic units in the modern economy. Indeed, only in this way can we obtain a really clear insight into the relationships determining the course of the economic process. . . . The number of relationships, however, which enter into such a micro-economic analysis of the total economic process is obviously so large that such a theory, with its implied attention to detail, is difficult to use for practical purposes. Economic policy needs easily comprehensible relationships between quantities which are few in number and essential for steering the economic process. For this reason it is necessary to reduce both the number of the quantities determining the course of the economic process and the number of the relationships between these quantities. We can do this if we aggregate the single economic units into large groups appropriate to the setting of the problem to be dealt with and confine our analysis to the relationships between these groups as supposedly homogeneous economic aggregates. . . . In this fashion we succeed—especially in the study of monetary relationships—in obtaining a greatly simplified picture of the relationships relevant to the process as a whole. . . . Naturally, such a macro-economic theory leads to results which are less enlightening and more uncertain than the results of a theory designed to explain the relationships between the smallest economic units. The significance of the results of a macro-economic theory and its quantitative reliability will be smaller the larger the size and the smaller the actual homogeneity of the groups with which the analysis operates. Nevertheless, macro-economic theory is simply indispensable for practical economic policy, because for technical reasons the individual households and firms are to a considerable extent beyond the reach of economic policy. Hence it is incumbent upon economic theory to make both types of analysis: a 'detail' analysis of the relationships between individual economic units and a 'bold-strokes-of-the-brush' analysis of the relationships between groups composed of individual economic units."

Fritz Machlup

The Johns Hopkins University

Economics—Principles and Applications. By JAMES HARVEY DODD and C. W. HASEK. (Cincinnati: South-Western Publishing Co. 1948. Pp. vi, 728. \$4.50.)

The authors of this introductory textbook belong to the category of educators whose objective is to appeal to the law of least resistance for sustained interest and effective comprehension of what economics is all about. The

central idea in this objective is to fit the presentation of materials to the intelligence of the average student, because what serves him "serves best the needs of all students." On this basis the students can get on "without much assistance from the instructor" who, it may be added, upon exacting attention might acquit himself of his stewardship by surprising everybody, including himself and the registrar. To be sure there is nothing amiss about the law of least resistance provided that the consequent law of large numbers does not involve a probability of self-deception. The accountancy of physical phenomena does not lend itself to social relationships, in which respect a tough proposition calls for a tough discipline.

The text is not organized on the analysis of the income approach, but follows the orthodox set-up. It starts with the nature and scope of economics and social organization, largely in an historical setting. Part II deals with a descriptive amplification of production of wealth and income and is followed by consumption of wealth and income. The next three sections deal with money and credit; value and price; and the distribution of national income. The last 250 pages are allotted to problems of labor-management; other economic problems, *i.e.*, business cycles, economic security, agriculture, war economy, international economic relationships; economic significance of government; and the challenge to American capitalism (socialism, communism, etc.)

There is no doubt that the authors have accomplished what they set out to do. They have been painstakingly meticulous in delivering a painless job for the student and a thoroughly commendable job for the registrant. Anything of this sort must necessarily involve an easy-going vocabulary, so that the fundamental economic tendencies can "be presented in as nontechnical form as possible." That is what is said in the preface, and there is no doubt of its superior negotiation. The presentation is further facilitated by numerous photographic reproductions of industrial and trade activities, historical charts, maps, several of the simplest of analytical diagrams, and questions and problems and suggested readings appended to each chapter. It all adds up to a well-lubricated delivery and may be considered an innovation for the instructor and students who, the publishers say, "have heard rumors from others that this book is really teachable and understandable."

Among the introductory chapters that deal with institutions in their historical and behavioristic aspects, the weakest ones are on the Evolution of the Economic Order, Mercantilism, and Capitalism. What strikes one foremost about these chapters is the retelling of shallow tracts that should have had the benefit of contributions of the Max Weber-Talcott Parsons-John U. Nef scholarship. The fellow who reads these sections will really get little that is decent about the genesis and evolution of capitalism. He will get very little about the fundamentally propelling impulses that underlie economic freedom and the transformation of economic institutions. Capitalism is not synonymous with the era of great inventions as the authors seem to indicate; nor can it be said that the great inventions occurred with the explosive force of mid-eighteenth century new departures. A brief survey of the industrial revolution should, at least, make mention of the intellectual de-

velopment of the period of the Reformation and Renaissance that exerted a great stimulus upon the natural sciences and technology, and of which the era of significant mechanical inventions is a subsequent development.

The authors' contention that "with reference to matters economic, prices are all important" is found wanting in a variety of price problems and analytical processes that serve the student as a foundation and as an instrument of refined and ultimate calculation and comprehension of price changes. Only one hundred pages are given over to value and price, of which about forty deal with government-controlled prices, and prices and the value of money. This last topic includes a two-page summary of the income theory of John M. Keynes. Admittedly, the sophomore will get a smattering of price theory and some of the underlying facts involved, but, as well, he might find himself in a state of bewilderment should he become ambitious and tackle some of the suggested readings. Again, the unfledged junior will take another look around should his curiosity urge him to dig somewhat deeper into the analysis of the distribution of national income. There is an amorphous mass of stuff here, especially on the theories of wages, interest, and profit that lacks the tooling of the marginal calculator and the principles of joint-cost relationships. An example of unconstrained detachment with which the analysis of the relations of profit to prosperity is rendered is the authors' application of Say's law of markets to the behavior of the business cycle in 1929 (p. 439). On the topic of loans it is held that government "is not limited as to the same means of repayment as is the individual, and it is not actuated by the feeling of personal need" (p. 421). Maybe it isn't! But as an unqualified account the statement displays an undisciplined temper about what the financial responsibility of government is.

The props for balanced production are to be found in the lessened inequality of incomes which rests on the quadrupled of social insurance, control of monopoly, encouragement of small business, and better housing and education. We'll conjecture that it is to be an education in the Marshallian sense—that public money may flow freely "to educate character, faculties and activities . . . toward a wider understanding of social responsibilities of economic chivalry."

ERWIN GRAUE

University of Idaho

Dictionary of Modern Economics. By BYRNE J. HORTON, JULIEN RIPLEY, JR., and M. B. SCHNAPPER. (Washington: Public Affairs Press, 1948. Pp. ix, 365. \$5.00.)

The contents of this book are perhaps best summarized by its half-title: *A Handbook of Essential Information Concerning the Basic Terms of Business, Finance, Commerce, and Modern Economic Society*. Its purpose is "to assemble and coordinate—primarily for the layman and incidentally for the college student—reasonably broad definitions of those terms which cover the economic facts of life."

On the whole, the book accomplishes its stated purpose with a high degree of success. Containing some 3000 entries, the dictionary includes widely

diverse topics and terms in the fields of economic theory, statistics, money and banking, international trade, public and private finance, business organization and practice, labor, and related areas. Numerous acts of federal legislation (chiefly in the New Deal period) and a number of court decisions are listed and briefly described. Of interest to the specialist in economics—principally for purposes of convenient reference—are the biographical sketches of some 125 or more leading economists, living and dead, with an indication of their contributions to the history of economic thought. Numerous bibliographical citations appear in connection with the definitions of specific terms. Considerable factual information, some nonessential, much practical, appears between the covers.

As measured by a rough "marginal utility" yardstick, the book appears to satisfy the criteria of comprehensiveness and carefulness, particularly for a first edition. Such terms, unfamiliar to the layman, as forced saving, the multiplier, the acceleration principle, the various "marginal" concepts, secular stagnation, the propensity to consume, the different degrees of monopoly, etc., are treated with sufficient clarity and accuracy to be useful to the intended audience. No pretense is made to definitive treatment of the kind afforded by the Encyclopedia of the Social Sciences, or required by the exigencies of a graduate curriculum in economics. Still, the bulk of the material has been prepared with sufficient care to satisfy the fastidious.

A few exceptions may be noted. On page 204, the "long and short haul principle" is defined as "an early practice among railroads by which a given shipment of goods would be carried a long distance at a lower rate than that charged for a shorter distance." By failing to add the words "over the same route" the authors have failed to identify the principle at issue; as the material stands, the statement and the related context are substantially incorrect. On page 325, one might wish for a more felicitous word, in a dictionary for laymen, than "justified": "Tariffs have been justified on the ground that they serve as means of national revenue, protect domestic industries, safeguard the wage level and standard of living [etc.]." A minor error appears at page 3 wherein the case of *Adkin v. Children's Hospital* is cited as involving the Oregon, rather than the District of Columbia, minimum wage law.

Suggestions that the book may be lacking in terms of balance are found at various places; e.g., "producer's surplus" is defined, but the more common "consumer's surplus" is omitted; "substitution effect" and "explicit cost" are included but "income effect" and "implicit cost" do not appear (although the latter is given as the definition of "imputed cost"); a minor federal agency such as the War Damage Corporation is listed, but the War Production Board is overlooked. A more substantial criticism is the spotty listing of federal court decisions. The eighteen or twenty cases cited, virtually all concerned with labor, are hardly representative of the major decisions of the Supreme Court affecting the American economy. (The usefulness of the list, especially for purposes of citation by the user, would be improved by including the volume and page number of the decisions.)

But these defects are for the most part minor, and are far outweighed by

the successful treatment of a multiplicity of commercial, financial, and business terms and institutions. The book is a welcome addition, and it should find wide use among businessmen, government workers, journalists, librarians, and others in need of a convenient reference manual in the field of economics. The authors are to be congratulated for their courage in undertaking a formidable task, and for their willingness to make currently available the fruits of their efforts at the risk of offense to sterile perfectionism.

General Education in the Social Studies. By ALBERT WILLIAM LEVI. (Washington: American Council on Education. 1948. Pp. xvii, 336. \$3.50.)

This volume is one of four reports of the Cooperative Study in General Education which the American Council on Education in collaboration with various colleges undertook with a view to exploring the possibilities of improving existing programs of general education. It derives its value and its practical usefulness as a source of suggestions for other colleges and universities from the fact that it describes in a very detailed fashion how some colleges approach the problem of setting up a two-year basic integrated course in the social studies; it also contains a helpful course outline as well as an extensive reading list. Beyond these practical features, the report provides a stimulating discussion of the general philosophy and assumptions which underlie the current emphasis on general education in the organization and planning of the undergraduate social studies curriculum. As such, it carries an important message to those economists who as specialists in one of the social sciences still view with skepticism this important trend in American education which seems to sweep the country like wildfire.

"The primary objective of curriculum planning in the social studies is to give an integrated and comprehensive picture of the nature of modern society" (p. 226). The traditional social science curriculum is said to have failed in this respect precisely because of its departmentalization. "Competing courses in history, sociology, political science, economics, anthropology, psychology, and geography exist side by side making their claims for student acceptance without any realization of the coordinate role which they play in the understanding of the social order as a whole" (p. 223). This failure of each isolated discipline to provide an understanding of the whole of society is in peculiar conflict with the presuppositions of a democratic society. Responsible participation in the democratic way of life depends upon an understanding of the social order as a whole as well as on the promotion of habits of democratic living, neither of which is achieved to an appreciable degree by isolated specialized studies. Even if specialized terminologies and techniques of analysis had not heightened the difficulties of intercommunication between the isolated social sciences, the free elective system together with an inadequate counseling system would in themselves be sufficient to defeat the attainment of a continuous and integrated general education in the social sciences. These are the considerations which seem to inspire the current emphasis on general education in the social studies which

found its earliest expression in the Columbia Contemporary Civilization course and which has now assumed the character of well established two-year integrated basic courses in numerous other colleges and universities.

The present report goes, however, far beyond the point of setting forth the general philosophy of the social studies program. It raises a host of detailed questions concerning the organization, content, administration and teaching of the program. Among these questions are the following: What is the proper approach in setting up the comprehensive social science course? Is it the historical approach, the problems approach or a systematic approach; or a combination of these three? Is the course to be conceived and planned as terminal, transitional or introductory and exploratory experiences in general education? At which time during the period of a four-year college education should the course be given? Should it be a free elective subject or should it be required of all students? Should the course be taught by one instructor or should the various parts be handled by different specialists?

According to the author, the best method of integrating the social studies for the purposes of providing an integrated picture of the nature of modern society is the conceptual scheme of cultural sociology and cultural anthropology. This broad conceptual scheme is believed to provide not only the most satisfactory combination of the three possible approaches mentioned above but determines also what constitutes the indispensable knowledge in the social studies and hence the indispensable content of the social studies course as it is conceived by the author of the report. This broad frame of reference which makes it possible to draw upon the results and techniques of analysis of all the social sciences leaves sufficient room for placing special emphasis on problems which at any given time seem to require special emphasis in the light of the needs of the students in each local situation. (One of the most original suggestions of the report which in fact is presented in such detail that it takes up a major part of the volume is the elaboration of an inventory of social beliefs and attitudes among students designed to reveal areas of special prejudice and bias on such problems as the public debt, labor relations, minority questions, etc.)

The report conceives of the social studies course as a terminal experience (that is, not preparatory or transitional to specialized work) primarily because it is thought that the demands of specialized work must be a matter of secondary rather than primary consideration in the light of the philosophy of general education. It considers the social studies program as a really co-operative enterprise of the social science faculty; as such, it should be constructed, taught and administered jointly by all within the division of the social sciences. It should be taught as a continuous course by one instructor and any attempt to turn over its constituent parts to the sociologist, the historian, the economist and the political scientist should be resisted. As an integrated course designed not only to convey the "indispensable knowledge" on the nature of the society we live in but also to develop a considerable degree of study skills, of critical thinking, and of attitudes indispensable for living in a democracy, the social studies program can not be a free

elective subject but should be required of all at the general education level of the American college.

The reviewer's criticism is not concerned with the basic philosophy of the social science program. On the contrary, I wholeheartedly concur with the view that the traditional social science curriculum conveys only a fragmentary and hence an inadequate and misleading picture of the society we live in. Because of these convictions it appears to me that the author takes it too easily for granted that the social studies course must be conceived as a terminal experience at the college level and cannot be planned as a transitional course to the specialized work which is to follow. I believe that this is due largely to the special approach favored which seems to neglect unduly the study of original source material and of the growth of ideas, basic concepts and theories in terms of which man has attempted to interpret the social and economic reality of his time. As far as the transition to specialized work in economics is concerned, it is easy to see for example that social studies programs which include the reading of original source material from the writings of let us say Thomas of Aquinas on just price, the mercantilists on the balance of trade and the effect of precious metal, Adam Smith, Ricardo, Malthus, Schmoller, Marx, Veblen, W. C. Mitchell, Beveridge, to name only a few, would provide a fruitful preparation to the more specialized work for the economics major. I am sure that the same applies to other disciplines.

The fact that such an approach would necessitate an adjustment of the traditional economics curriculum and that very little has been done to this effect even in institutions which place greater emphasis on original source material and the historical approach does not defeat our argument. The trouble lies rather in the fact that only a small group in each department is called upon to participate in the social studies program and that as a result the majority of the members never acquire a first-hand insight and interest in the subject matter of the course and hence are unable to judge its potentialities as an introduction to their own specialized work. As far as the transition to specialized work in economics is concerned, probably the best stepping-stone would be provided by a course in the history of economic thought offered concomitantly with a basic principles course in the junior year. Doubtless a survey of alternative approaches to the organization of social studies programs and a detailed evaluation of social science courses in existence at other institutions would have provided a clue as to how this transition from general to specialized education might be achieved to the mutual advantage of both. It is to be regretted that the cooperative study in general education did not devote any attention to such a comparative evaluation of existing general education programs in the social studies; such an evaluation remains one of the most important needs at this time when the whole problem of social studies courses is under scrutiny by colleges and universities which so far have introduced such programs only on an experimental basis.

Economic History; National Economies

The Development of Southern Sectionalism, 1819-1848. By CHARLES S. SYDNOR. Vol. V of *A History of the South*, edited by W. H. Stephenson and E. M. Coulter. (Baton Rouge: Louisiana State Univ. Press. 1948. Pp. xii, 400. \$6.00.)

The South During Reconstruction, 1865-1877. By E. MERTON COULTER. Vol. VIII of *A History of the South*. (Baton Rouge: Louisiana State Univ. Press. 1947. Pp. xii, 426. \$5.00.)

With the justifiable pride that accompanies distinct achievement, Louisiana State University and the University of Texas have launched their new series in the *History of the South*. The initial volumes by Charles S. Sydnor and E. Merton Coulter provide ample evidence that a major contribution to American historiography is in the process of completion. As a work of synthesis, drawing upon the findings of countless individual monographs and primary sources, this series will offer a valuable tool to many scholars interested in regional developments.

Adhering to the general method utilized in previous multi-volume cooperative projects, the editors have contemplated a ten-volume series, entrusting the responsibility for each study to a capable specialist in some period of Southern history. Although the division into time units occasionally may seem to be arbitrary, since the forty-one years covered jointly by these two volumes receive as much space as the entire colonial period, one cannot deny that standards of current interest, and, to a lesser degree, the availability of source material, virtually determine the emphasis.

The years which were assigned to the present authors are certainly of crucial importance. The vindictive and unfortunate Reconstruction era was largely the consequence of bitter sectional antagonisms that had developed during the preceding generation. A reading of Professor Sydnor's book affords an opportunity to understand how the South came to assume an increasing attitude of local self-consciousness. In explaining the transition from nationalism to sectionalism, the author stresses the gradual reduction of Southern influence that occurred between 1819 and 1848. "At the beginning of the period under review," we are told, "Southern politicians and statesmen well-nigh dominated the Federal government; before it was ended they had seen their region decline to a subordinate political position." While the interpretation may at times underestimate the continuing influence of Southern leaders in high national office and the voice of the Southern wing of the Democratic Party, the chapters on political sectionalism, "Regionalism in Mind and Spirit," and "Party Allegiance or Sectional Patriotism?" provide splendid insight into the real and occasionally fancied grievances of the South. This defensive position was eventually restated as a positive affirmation of the virtues of slavery and the plantation economy.

In *The South During Reconstruction*, Professor Coulter's work, this trend is likewise in evidence. Reacting against the physical devastation of the war and the policies of Congressional Reconstruction, the latent resentment of the South crystallized in the activities of the Klu Klux Klan. Quite legiti-

mately the author observes that the poor whites, with whom the Negro had traditionally come into economic competition, were "at the bottom of nearly every assault and battery on the freedman." However, the apparent admiration for the Klan's "artistic" and "humorous" techniques, which achieved "remarkable results" through "cleverly organized" intimidation, sometimes colors the account. Considerably more satisfactory is the description of the methods of social and economic ostracism that were employed to stamp out the vestige of white radicalism. By 1877, as a result of southern resistance and the emergence of moderate national leadership, the former Confederate states were in a position to resume their standing in the Union. The radical version of Reconstruction, in the opinion of the author, had proved to be a dismal failure.

In allowing a comparison of the South's economic status before and after the War between the States, these volumes are especially useful. During both periods the South was vulnerable to the consequences of sudden depreciation in the price of cotton, invariably the chief money crop. Although the economy in each instance was identified with rural society, Professor Coulter points to the growth of urban population during the decade which began with 1860. Its relationship to increased industrialism was generally valid, in spite of the fact that the Carolinas and Georgia, whose urban growth was less than the national average, progressed considerably as manufacturing states. Nevertheless, the account gives the dubious impression that no Negroes worked in the cotton mills because they were incapable of attending to the looms with efficiency. Certainly this interpretation fails to take cognizance of the successful prewar experiment with Negro labor conducted by the Suluda River, South Carolina, textile factory. Nor does it consider the obstacles to Negro employment which were created by the hostility of white labor and the various state license requirements that confronted the freedman seeking non-agricultural work. Similarly, Dr. Sydnor's book, in its attempt to stress the predominance of agriculture, perhaps underestimates the significance of Southern manufacturing as a whole. In maintaining that there were only about 100,000 persons engaged in Southern manufacturing at the time of the Census of 1820, the approximation tends to overlook the large numbers of slaves who were trained in plantation handicrafts. These occupations were not listed in most census reports, but they are too important to be ignored. However, the author has honestly acknowledged that he is aware of the imperfections of the early tabulations, and "is using the census without interpolating warnings and cautions" only because of a scarcity of better source of information.

Each of the writers also considers the significant question of Southern economic vassalage. Although he recognizes that New York's merchants as early as 1822 had "secured most of the business of handling goods that went south in exchange for Southern staples," Dr. Sydnor repudiates the notion that the South's export trade was really under external domination. Even during the 1830's there was little more than oratorical criticism of alleged Northern interference with the direct trade relations between the cotton states and the rest of the world. To Dr. Coulter, on the other hand, the

problem seems far more acute. Speaking of the long-standing dependence upon the North, he maintains that the situation became even more malignant during the era of Reconstruction. The subject of plantation ownership and investment by absentee Northern capitalists receives special attention, though it is largely slighted in the other book. And yet the problem is of major consequence if one is to understand the motives of the secessionist element in New York City during the Civil War.

A further comparison of the two volumes demonstrates that Professor Coulter, to a greater extent than his colleague, has concentrated upon the internal condition of the South, deliberately ignoring many simultaneous federal developments. Thus even the Congressional debates over Southern Reconstruction receive only abbreviated attention. In Dr. Sydnor's study the national policies affecting the South, such as the Missouri Compromise, the presidential elections, and the Nullification movement, are explored with more adequate detail. The key to this difference perhaps lies in the fact that the South had taken an active part in the ante-bellum politics of the nation, whereas the years immediately after the war witnessed a period of substantial eclipse.

In general, the two books adhere to the same method, providing scholarly and well-written evaluations of Southern life. Both works seek to achieve a balance in the various questions selected for discussion, offering appraisals of such widely divergent topics as transportation, agriculture, local government, education, and social theory. The bibliographic essays contain useful commentaries on the extant manuscript and printed sources. While the interpretations of native Southern institutions are relatively uncritical, this series, when completed, will provide our basic storehouse of information about the region for many years to come.

LEONARD PRICE STAVISKY

*New York State Teachers College
Oswego, New York*

New Paths for Japan. By HAROLD WAKEFIELD. (New York: Oxford Univ. Press. 1948. Pp. viii, 216. \$3.75.)

Since the opening phases of the occupation of Japan the problem of economic policy has been one of foremost consideration by the Allied authorities. Initial methods of adjusting the economy of Japan to a modern, peacetime social system followed a generally non-conservative pattern. In recent months, however, economic policy for Japan has undergone significant changes bordering on more moderate principles. There is under way a testing of the relative empirical values of given sets of principles and policies in relation to the peculiarities of Japanese society.

New Paths for Japan, a sequel to the Royal Institute of International Affairs, Chatham House Study Group report, *Japan in Defeat*, is an attempt to clarify many problems of economic policy. It has an added value to American economists interested in Japan because it represents the thinking and interpretation of a British authority. The book is concerned in several

sections with descriptive political material, but this is supplementary to concise treatment of economic matters. The various trends resulting from the application of respective economic policy can be traced clearly.
